## INDEX

129

## NAME INDEX

Dr C G ), The Periodometer, 684  
 ), and O Smetana, The Periodate Potential, 915  
 Prof J J ), elected President of the American  
 Association for the Advancement of Science, 127  
 (Prof G ), elected an Associate of the Royal Astro-  
 nomical Society, 894  
 am (H ), The Maintenance of a Room at Constant  
 Temperature, 214  
 (Bishop of), Challenger, West Africa, 862  
 man (J ), 1007

Andrieux (L ), and D Barbetti, The Alkaline Borides, 915  
 v Angerer (Prof E ), Wissenschaftliche Photographie  
 eine Einführung in Theorie und Praxis (*Review*), 814  
 Angus (Prof R W ), Hydraulics for Engineers including  
 Turbines and Pumps and Unsteady Motion (*Review*), 492  
 Antoniadis (E M ), Mars during the Last Two Oppositions,  
 765  
 Appell (P ), et Prof É Goursat, Théorie des fonc-  
 tions algébriques et de leurs intégrales. Deux éd.

- Avrard (P ), [E Chauvenet and], Determination of Barium Sulphate in Iron Ores, 770
- Awbery (J H ) The Water-Content of Saturated Air at Temperatures up to  $100^{\circ}$  C, 254, and Dr Ezer Griffiths, The Basic Law of the Wet-and-Dry-bulb Hygrometer, 254, The Specific Volumes of some Gaseous Refrigerants, The Latent Heat of some Refrigerants, 254
- Babbage (D W ), awarded a Smith's Prize of Cambridge University, 445
- Baccaredda (M ), [L Passerini and], Researches on Spinels (4), 142
- Bacharach (A L ), Plant Chemistry (*Review*), 886
- Bagi (B B ), Plane Trigonometry (*Review*), 44
- Bailey (C R ), and A B D Cassie, Infra-Red Absorption Spectra of the Oxides of Chlorine, 652
- Bailey (K C ), [W S E Hickson and], Inhibition of Chemical Reactions (5), 553
- Bailey (R W ), and A M Roberts, Creep Tests on Steel for Steam Plant, 729
- Bailey (Prof V A ), Photoelectrons and Negative Ions, 166
- Bailly [Remlinger, Manouélian, and], The Nerve Centres of the Tortoise inoculated with the Rabies Bacillus, 69
- Baily (J L ), Life History of a Fresh-water Snail, 907
- (E C ), [M A Grossmann and], High Speed Steel 529
- Barclay (Dr A E ), appointed to the Morris Radiological Research Fellowship at the Mount Vernon Hospital, 92
- Bardet (J ), [C Levaditi, A Tchakirián, and A Vaisman], The Therapeutic Properties of Indium in Trypanosomiasis and in Experimental Syphilis, 374
- Barger (Prof G ), Ergot and Ergotism, 335
- Barker (Prof A F ), *Ovis astore*, a Three-Coated Sheep, 436
- Barker (E F ), Raman Lines and Infra-Red Bands in Nitrous Oxide, 132
- Barker (Dr S G ), Relation of Science to Industry, 933
- Barley (Major L J ), The Riddle of Rationalisation (*Review*), 882
- Barlow (N ), The Voyage of the *Beagle*, 439
- Barnard (J E ), A New Illumination Device for Microscopy, 199
- Barnes (A A ), Rain-gaugings near Belper and Duffield, 68
- Barnes (Prof H T ), and T C Barnes, Biological Effect of Associated Water Molecules, 691
- Barnes (L L ), and R C Gibbs, Positive Ions of Mass, 220, 946
- Barnes (T C ), Physiological Effect of Trihydrol in Water, 735, [Prof H T Barnes and], Biological Effect of Associated Water Molecules, 691
- Baroni (A ), Measurement of the Parachor applied to the Study of the Constitution of Polysulphides

Lakes and Dyed Fabrics, 843  
 dams; Jr (Prof N I), [Prof L Page and], Principles of Electricity an Intermediate Text in Electricity and Magnetism (*Review*), 332  
 die (R. H.), [death], 786, [obituary article], 893  
 lkin (R.), Microlepidoptera, of Eastbourne, 467  
 ller (S.), and O Theodor, Mediterranean Kala Azar (6), 662  
 rian (Prof E D), and others, Physiological Basis of Sensation, 67  
 el (H A.), W S Gorton, and R W Chesnut, A Modern Telephone Cable, 274  
 ken (A C), On the Orthogonal Polynomials in Frequencies of Type B, 254  
 ken (Dr R G.), awarded the gold medal of the Royal Astronomical Society, 92  
 ertus Magnus His Scientific Views, 266  
 ight (H M.), The American National Park Service, 933  
 ington (Major), and others, Road Traffic Signalling, 163  
 ick (C R.), The Primitive Mind and Modern Civilization (*Review*), 79  
 ssandro (B.), Oxidation of Starch, 905  
 xander (E.), [Prof G Hevesy and], Intensity Ratio of Fluorescent X-Ray Lines, 315  
 ngton (Rev Dr C.), The Education of the Average Man, 393  
 n [Hyde, Tomlinson, and], Performance of Gears, 538  
 ock (H.), Simpler British Coinage, 198  
 n (Prof H S.), Disintegration of Atomic Nuclei, 830  
 son, Bishop, Sommer, and Christensen, Elements 85 and 87, 657  
 and (Prof A J.), The Drumm Traction Battery, 386  
 and G H Skrimshire, Determination of Substances, with Special Reference to M Lowry and], Refractive Dis- of 'Optical Exaltation', 33  
 ures of the Wolf-Rayet Stars,  
 an, Ensilage, 172  
 A New Type of True Acetylene  
 ropine, 590  
 and], Individual Specificity of  
 ccurring Spanish-African Fever,  
 he Pig to African Strains of  
 n, 410  
 ), The Cry of Tin, 651, Viscosity  
 ex Motion in Vibrating Columns  
 William), [death], 338, [obituary  
 Massey and], Leaf Curl Disease

1 et 2 (*Review*), 600  
 Appleton (Prof E V) and F W Chapman, The Collisional Friction experienced by Vibrating Electrons in Ionised Air, 553, and Prof S Chapman, Suggested Wireless Observations during the Solar Eclipse of August 31, 1932, 757, and R Naismith, Some Measurements of Upper Atmospheric Ionisation, 841  
 Argue (G H.), [Dr E H Boomer, H E Morris, and], Apparent Formation of Copper Carbonyl, 438  
 Armellini (G.) A New Cosmogonic Interpretation of the Equipartition of Energy among the Stars, 215, and G Conti, Variations of Atmospheric Absorption and various Observations, 807  
 Armstrong (Dr E F) Hydrogen and its Uses, 825, and K F Armstrong, The Glycosides (*Review*), 886  
 Armstrong (G.), Electrochemical Periodicities, 613  
 Armstrong (Prof H E.), Back to the Land (*Review*), 112, Faraday at the Sign of the Hexagon, 787, Light and Sexual Periodicity, 906, The Mind Judicial (*Review*), 739, The Iron and Steel Industry, 268, Waste in Education and Chemistry, 896  
 Armstrong (K F.), [Dr E F Armstrong and], The Glycosides (*Review*), 886  
 Arnaud (F W F.), elected President of the Society of Public Analysts, 433  
 Arnaud [Cuboni and], Vitamin B and Phytase, 101  
 Arnot (Dr F L.), Molecular Dissociation by Electron Impact, 617  
 Arup (P S.), The Iodine and Thiocyanogen Value of Irish Butter, 806  
 Ashley (Muriel), [Dr F A Jenkins and], Nuclear Spm of Phosphorus from the Band Spectrum, 829  
 Ashmore (S E.), Occurrence of Fog with Unsaturated Air at Grayshott, Hants, 410  
 Ashworth (Miss Dorothy), *Puccinia Malvacearum*, a Homothallic Rust Fungus, 620  
 Askania-Werke A G., A Prismatic Derivator, 126  
 Askew (F A.), R B Bourdillon, H M Bruce, R K Callow, J St L Philpot, and T A. Webster, Crystalline Vitamin D, 178  
 Astbury (W T.), T C Marwick, and J D Bernal, X-Ray Analysis of the Structure of the Wall of *Valonia ventricosa* (1), 178  
 Aston (Dr F W.), Isotopic Constitution of Lead from Different Sources, 649, Measurements on Isotopes, 172  
 Athlone (Earl of), elected Chancellor of London University, 176  
 Atkins (Dr W R G.), Preparation of Sulphuric Acid free from Nitric Acid, 98  
 Audubert (R.), and Mlle Cécile Stora, The Photovoltaic Properties of Cadmium Sulphide, 734  
 Auer (V.), and Mme Poulenc-Ferriand, Cupric Carbonate, 554

Bain (W A), [Shih-Chen T'ao and], Employment of Intra-cardiac Injections of Adrenaline in Asphyxia, 254

Baker (E C. Stuart), Protective Coloration of Birds' Eggs, 247

Baker (J N L), A History of Geographical Discovery and Exploration (*Review*), 43, The Climate of England in the Seventeenth Century, 698

Baker (J R), and R M Ranson, Factors affecting the Breeding of the Field Mouse (*Microtus hirtus*), (1) Light, 253

Bald and Geoffrey, Spotted Wilt of Tomatoes, 692

Baldwin (E), [D M Needham, Dr J Needham, J Yudkin, and], A Comparative Study of the Phosphagens, 373

Balfour (H), Thorn-lined Traps, 511

Ballance (Sir Charles), awarded the Lister Medal of the Royal College of Surgeons of England, 756

Ballantine (Prof J P), The Macmillan Table Slide Rule (*Review*), 9

Ballard (Dr P B), Teaching of Mathematics (*Review*), 742

Balls (Dr W L), Rapid Estimation of Water-Content in Undisturbed Soil and in Bales of Cotton, 505

Balozet (L), [C Nicolle and], Swine Fever transmissible to Man, 915

Bamber (Ruth C), (Mrs Bisbee), An Inherited Abnormality in Rhode Island Red Poultry, 762

Banachewicz (Prof T), Selenographical Tables and Coordinates, 208

Bancroft (W D) and J W Ackerman, The Fading of Lakes and Dyed Fabrics, 843, and J E Rutzler, jr, Reversible Coagulation in Living Tissue (6 and 7), 291, Reversible Coagulation in Living Tissue (8), 483, R S Gutsell, and J E Rutzler, jr, Reversible Coagulation in Living Tissue (9), 591, R S Gutsell, and J E Rutzler, jr, Reversible Coagulation in Living Tissue (10), 734

Band (W), [Shih-Chen T'ao and], Some Thermomagnetic Effects in Nickel and Iron, 373

Banergi (Dr B N), Meteorology of the Persian Gulf and Mekran, 659

Bannister (F A), Distinction of Pyrite from Marcasite in Nodular Growths, 625

Bar (Prof R), Atoms and Molecules as Fitzgerald Oscillators, 505

Baranov (V), and L Kurbatov, The Radium Content of the Petroliferous Waters in the Grozny District, 34

Barbetti (D), [L Andreux and], The Alkaline Borides, 915

Barbieri (G A), Compounds of Bivalent and of Trivalent Silver, 70

Barbour (Prof G B), Pleistocene Climates of North China, 474

Barrett (C S), [Dr R F Mehl, J W Smith, and], Segregation of Cementite from Austenite, 313

Barrett (Sir James W), Vocal Powers and Eyes of Kangaroos, 689

Barrington (R E D), 'Bullying' amongst Birds, 395

Barrows (W P), [W Blum, A Brenner, and], Chromium Plating, 101

Bass (Dr L W), [Dr P A Levene and], Nucleic Acids (*Review*), 44

Bassindale (R), [Dr B A Southgate, F T K Pentelow, and], Death of Fish in the Tees Estuary, 129

Bassler (R S), [E O Ulrich and], Cambrian Conchostrophia, 367

Bastien (P), [A Portevin and], The Principal Factors affecting the Flow of Pure Metals, 519

Bastow (S H), and F P Bowden, Contact of Smooth Surfaces, 438

Basu (S), [Dr Sobhag Mal, B N Desai, and], Structure and Development of Temperature Inversions in the Atmosphere, 97

Bateman (Prof H), Partial Differential Equations of Mathematical Physics (*Review*), 850

Bather (Dr F A), Protection of Herbarium Specimens, 655, re-elected President of the Palaeontographical Society, 827

Batjer (L P), [J W Crist and], Stone Cells of Pear Fruits, 207

Battegay (M), and J Meybeck, The Amino-Sulphonamides, 326

Baudouin (Dr M), and C B Whelan, Diorite Axes from Ireland, 171

Bauer (Dr L A), [obituary article], 71

Bawn, Adsorption, 320

Bawn (C E H), [Dr W Lochte-Holtgreter and], Photochemical Disposition of Phosphide, 869

Beadle (L C), [Dr E B Wilson and], The Clines in Tropical Lakes, 16

Bearden (J A), X-Ray Wave-lengths, 16

Beathe (Prof J M), Medical Bacteriology, 16

Beauvais (G), [C Gutton and], The Discharge of a Capacitor, 410

Beck (C), elected President of the Royal Society, 164

Becker (F E) and Co., Laboratory Equipment, 16

Beckett (H E), [Dr E B Wilson and], The Measurement of Radiation, 16

Bequerel (P), The Discharge of a Capacitor at Low Temperatures, 16

Bedell (Prof F), [Dr E B Wilson and], The Discharge of a Capacitor, 16

- de Beer (G R), Morphology and Evolution (*Review*), 490, [L H Dudley Buxton and], Neanderthal and Modern Man, 940
- Běhounek (Dr F), and Prof J Heyrovský, Úvod do Radioaktivit (*Review*), 816
- Behrend (B A), [death], 714
- Bekker (J G), [Dr C Rimington and], Is Preformed Cystine essential to Sheep for Wool Production? 687
- Bell (J), (King of the), Natural Reserves in the Belgian go, 933
- Bell (J), Photosynthesis of Carbohydrates *in Vitro*, 170
- Bell (R M), Broadcast Reception in the United States, 681
- Benedict (F G), and E L Fox, Body Temperature and Heat Regulation of Large Snakes, 291, E L Fox, and V Coropatchinsky, The Incubating Python, 843
- Bengough (G D), and L Whitby, Magnesium Alloy Protection by Selenium and other Coating Processes, 481
- Bennett (M G), The Visual Range of Lights at Night and its Relation to the Visual Range of Ordinary Objects by Day, 410
- Benson (S B), and A E Borell, Habits of Californian Red Tree Mouse, 99
- Bentham, Jeremy, Philosopher and Social Engineer, Centenary of the death of, 912
- Bentley (W A), and W J Humphreys, Snow Crystals (*Review*), 778
- Bergner (A Dorothy), and A F Blakeslee, Cytology of the *Ferox-quercifolia-stramonium* Triangle in *Datura*, 843
- Berman (L), The Star 70 Ophiuchi, 874
- Bernal (J D), Crystal Structures of Vitamin D and Related Compounds, 277, Properties and Structures of Crystalline Vitamins, 721, Rotation of Molecules in Crystals, 870, [W T Astbury, T C Marwick, and], X-Ray Analysis of the Structure of the Wall of *Valonia ventricosa* (1), 178
- Bernardini (G), The Variation of Penetrating Radiation with Zenith Distance, 578
- Bert (L), and E Ander, A New Type of True Acetylene Compound, Phenoxypopine, 590
- Berthelot (A), The Unit of Length employed in the First Measurements of the Earth's Circumference, 842
- Bertrand (G), Can Gold be considered as one of the Elements of Living Matter? 447
- Beurlen (K), Vergleichende Stammesgeschichte Grundlagen, Methoden, Probleme unter besonderer Berücksichtigung der höheren Krebse (*Review*), 745
- Bhagavantam (S), Oscillations of the Methane Molecule, 830, The Spinning Photon and its Scattering by Molecules, 167, [Sir C V Raman and], Experimental Proof of the Spin of the Photon, 22, The Spin of the Photon, 62, and S Venkateswaran, Polarisation of Raman Scattering, 580
- Bhaugava (Saligram), [Prof M N Saha, J B Mukerji, and], Complex X-Ray Characteristic Spectra, 435
- von Biesbroeck (Prof G), Cometary Observations at Yerkes Observatory, 837
- Bigelow (Prof H B), awarded the Agassiz medal of the US National Academy of Sciences, 92, Oceanography its Scope, Problems, and Economic Importance (*Review*), 7
- Bigourdan (G), [death], 570, [obituary article], 643
- Bilham (E G), Measuring Atmospheric Pollution, 103
- Billington (Prof W), [death], 270
- Bills (C E), and F G McDonald, Synthesis of Vitamin D, 50

 Charles II Exhibition in London, 308  
 Chaucer on the Astrolabe Second and abbreviated edition revised by Dr R T Gunther (*Review*), 300  
 Chemical and Photochemical Reactivity, 340, and Physical Apparatus, Supplementary Catalogue of, F E Becker and Co, 164, Constitution and Taste, Relationship between, A L Fox, 735, Engineering, Researches in, 91, Elements at a Glance (*Review*), 851, Embryology Dr J Needham, 3 vols (*Review*), 183, The Sphere of (*Review*), 183, Reactions, Inhibition of, (5), W S E Hickson and K C Bailey, 553, Society, Glasgow Meeting of the, Presidential Address by Prof G G Henderson, 516, Warfare and Disarmament, 809, A Marshall, 906  
 Chemie, organischen, Theoretische Grundlagen der, Prof W Huckel 2 Band (*Review*), 40  
 Cheminement de la pensée, Du, E Meyerson, Tome 1, 2, et 3 (*Review*), 42  
 Chemischer Handatlas, W W Meissner (*Review*), 851  
 Chemistry and Chemical Technology, Bibliography of Bibliographies on, Second Supplement, 791, Annual Reports on the Progress of, for 1931 Vol 28 (*Review*), 779, Applied, Progress of, Reports of the Vol 16, 1931 (*Review*), 635, at the Centenary (1931) Meeting of the British Association for the Advancement of Science, 491, Capillary, A Phenomenon of, R Dubrisay 698, Federal Council for, Report for 1931, 463, Higher, for Schools (*Review*), 919, Inorganic Prof T M Lowry Second edition (*Review*), 704, a Textbook for Colleges and Schools, Dr E J Holmyard (*Review*), 919, and Theoretical, Dr F S Taylor (*Review*), 919, Institute of, Annual General Meeting, presentation of Meldola Medal to Dr G F Marrian, re election of Dr G C Clayton as President, 393, Organic General and Specialised, Prof C S Gibson (*Review*), 40, Recent Advances in, Prof A W Stewart Sixth edition 2 vols (*Review*), 853, The Principles of Third edition, Prof J F Norris (*Review*), 40, Physical A Sutchie (*Review*), 919, Problems in Practical, F A Philbrick (*Review*), 80, Progress in (*Review*), 354, Recent Advances in, Dr S Glasstone (*Review*), 354, Plant, A L Bacharach (*Review*), 886, Progress of, 491  
 Cherry Fruit Tree, Order respecting the, 790  
 Children we Teach The, Seven to Eleven Years, Dr Susan Isaacs (*Review*), 673  
 Children's Drawings The Psychology of, from the First Stroke to the Coloured Drawing, Helga Eng Translated by H S Hatfield (*Review*), 745  
 Chillingham Herd of Wild Cattle, The, 241, 465  
 Chimie, La Maison de la, Paris, 865  
 China North, Pleistocene Climates of, Prof G B Barbour, 474, Dr D Black, 475, Western, Cave Exploration in, D C Graham, 754  
 Chinese Fossil Man, Implements of, Sir A Smith Woodward, 784, Materia Medica, Prof B E Read, 444  
 Chlorine Hydrogen and, in the Presence of Oxygen, Photochemical Reaction between, M Ritchie and Dr R G W Norrish, 243, Oxides of, Infra-Red Absorption Spectra of the, C R Bailey and A B D Cassie, 652  
 Chocolate Confectionery and Cocoa, The Chemistry, Flavouring and Manufacture of, H R Jensen (*Review*), 189  
 Chords, Maximum and Minimum, Normal to a Hyper-surface, Luisa Pelosi, 554  
 Chromic Chlorides, The Hydrated, A Recoura, 374  
 Chromium Plating, W Blum, W P Barrows, and A Brenner, 101  
 Chromosome Studies and Plant Breeding, Dr C D Darlington, 445  
 Chromosomes Individuality of, Grégoire, 656, Structure and Division of, Dr S Hedayetullah, 547  
 Chrysotile Asbestos in Canada, J G Ross, 199  
 C I E Colorimetric Standards and their Use, T Smith and J Guild, 770  
 Cigarette Habit, The, Dr J D Rolleston, 609  
 Cinchona and Quinine The Ready Supply of, an Urgent Need, 413  
 Cinematographer's Handbook on Movie Making, The Amateur, R Dykes (*Review*), 814  
 Circular Dichroism, Influence of the Nature of the Chemical Linkages on the production of, J P Mathieu, 69  
 City and Guilds of London Institute, Sir William J Pope elected Chairman of Council of the, 396  
 Civil Engineers, Institution of, Awards of the, 719  
 'Cleistogenes' in certain Grasses, Occurrence of, Annie A Poulter, 690  
 Climate of Southern Rhodesia, 515  
 Clocks Talking, designed for the Telephonic Distribution of the Time, E Esclançon, 662, worked from the Electric Supply Mains, 645  
 Cloth Fulling, Early, E Kilburn Scott, 16  
 Clouds Alto-cumulus, Formation of, C S Duist, 475, Form and Height of, 66, High in the Stratosphere, Prof S Chapman, 497, Iridescent Types of, H S Wynne-Edwards, T S Dymonds, 798, Mother-of-Pearl, over Scandinavia in January and February 1932, Prof C Stormer, 941  
*Clupea harengus*, Origin of Erythrocytes in, C C John, 253  
 Coacervation, Dr R S Tjaden Modderman and Dr L W J Holleman, 654  
 Coagulation, Reversible, in Living Tissue, W D Bancroft and J E Rutzler, Jr (6 and 7), 291, W D Bancroft, R S Gutsell, and J E Rutzler, Jr (9), 591  
 Coal Carbonisation of, 30, Measures of Belgium, The, Prof A Renier, Prof P Pruvost, Prof A E Trueman, 29, Oil and Petrol from, Prof C H Lander, 640, 676  
 Coals, Northumbrian, 230  
 Cobalt Sulphate, Anhydrous, The Magnetic Properties and Crystalline Structure in the Different Varieties of, R Hocart and Mlle A Serres, 141, Tetravalent, The Magnetic Moment of, Mlle A Serres, 178  
 Cobaltous Salts, Aqueous Solutions of, The Preparation of Two Types of, A Lallemand, 178  
 CO Bands, Structure of the Third Positive Group of, Dr G H Dieke and J W Mauchly, 546  
 Coffee, Fermentation of, A Pernier, 374  
 Collembola in England, Swarming of, F A Turk, 830, Resistance of the Eggs of, to Drought Conditions, Dr J Davidson, 867  
 Colloidal Complexes, Commercial, M Chopin, 254, Silver, Magnetism of Precipitates of, Dr V I Vaidhyanathan and B S Puri, 170, Solutions Flocculation of, Photosensitising Action of Colourless Fluorescent Materials on the, J Bouchard, 807, Study of, by the Polarisation of the Light Diffused by them, A Boutaric and C Tournier, 34, The Specific Inductive Capacity of, T Nanty and M Valet, 590

- Colloids, Dr E S Hedges, Dr A Ferguson (*Review*), 299  
 Colombian Archaeology, J A Mason, 282  
 Colonial Office Appointments, 92, 241, 574, 718, Forests, The, and their Staffs, 845  
 Colorado, Eastern, Archaeology of, Dr E B Renaud and others, 324  
 Colour Index, The Absolute, and Stellar Statistics, P Rossier, 107, Science, Dr W Ostwald Part 1  
 Colour Theory and Colour Standardisation Translated, with an Introduction and Notes, by J Scott Taylor (*Review*), 453, Standardisation, J Guild (*Review*), 453  
 Coloured and Colour Breeding, The, T W Hogarth (*Review*), 925  
 Comet A New Faint, 1931 e, 173, New, 585, 694, Orbits, The Problem of, G Tiercy, 107  
 Cometary Observations at Yerkes Observatory, Prof G van Biesbroeck, 837  
 Comité International d'Histoire des Sciences, 310  
 Commonwealth Fund Fellowships, Awards of, 804  
 Communication Networks, Prof E A Guillemin Vol 1 (*Review*), 301, Systems, Modern, Dr F Luschen, 682  
 Compounds, Formation of, in Aqueous Solution of Thieryl Chloride and Alkaline Chlorides, E and R Chauvenet, 807  
 Concrete or Reinforced Concrete Works, Testing, especially Barrages, by Means of Sound, A Coyne, 519  
 Conductivity Equation, Shedlovsky, 801  
 Conical Diaphragms and Sound Reproduction, Dr N W McLachlan and G A V Sowter, 62  
 Coniferae including Gnkoaceae A Handbook of, W Dallimore and A B Jackson Second edition (*Review*), 631  
 Contraception (Birth Control) its Theory, History, and Practice a Manual for the Medical and Legal Professions, Dr Marie Carmichael Stopes New edition (*Review*), 455, The Practice of, an International Symposium and Survey Edited by Margaret Singer and Dr Hannah M Stone (*Review*), 922  
 Contraceptive Advice, Bureau of, Analysis of Work of, a, Prof R Pearl, 864  
 Coombs Deposits at Greenhithe, Kent, Geological Sequence of, J P T Burchell, 96  
 Co-operation, International, 217  
 Co-ordination of Scientific Digests, 181  
 Cope, Master Naturalist, Prof H F Osborn, with the Co-operation of Helen Ann Warren (*Review*), 299  
 Copper and Silver Compounds, Bivalent, Magnetism of, Sugden, 513, Carbonyl, Apparent Formation of, Dr E H Boomer, H E Morris, and G H Argue, 438, in Relation to Low Stresses, Properties of, O F Hudson and J McKeown, H J Tapsell and A E Johnson, 446, in the Presence of Iron and certain other Metals, Determination of Minute Amounts of, L G Haddock and N Evers, 806, Silver Alloys, Pickling of, in Dilute Sulphuric Acid, A Borloz, 771  
 Cormorant Fishing in China, B Laufer, 231  
 Corn Grain, Preservation and Productivity of, G Tallarico, 70  
 Coronal Lines, Origin of the, Dr T L de Bruin, 468, Dr R Frerichs, 901, Prof H Dingle, 902  
 Coroner's Law in the United States, G H Weinmann, 198  
 Corpuscular Radiation generated in the Atmosphere, Action of the Terrestrial Magnetic Field on a, B Rossi, 952
- CORRESPONDENCE
- $\alpha$ -Particles, Anomalous Scattering of, by Hydrogen and Helium, H M Taylor, 56  
 Absorbed Organic Compounds, Dependence of Angle of Contact on the Constitution of, A B Cox, Elsie E Wark, and Dr I W Wark, 871  
 Acquired Characters, The Inheritance of, Prof E W MacBride, 900  
 Adders, Hibernation of, Dr N Morrison, 473  
 Adrenal Medulla, Function of the, J L Svirbely and Prof A Szent-Gyorgyi, 541  
 Agricultural Pamphlet, An, Sir John Russell, 133  
 Air Column Resonances and Symmetrical Modes of Truncated Conical Shells (Loud Speaker Diaphragms), Dr N W McLachlan, 202  
 Albertine Rift, The Tectonics of the, E J Wayland, 762  
 Albertus Magnus as Chemist, Prof F Paneth, 612  
 Allelomorphs in Mice, A New Series of, Prof L C Dunn, Dr R A Fisher, 130  
 Amoeba, Proper Name of the, Prof T D A Cockerell, 726

- Snail, Fresh-water, Life History of a, J L Baily, 907
- Snakes, Large, Body Temperature and Heat Regulation of, F G Benedict and E L Fox, 291
- Snow and Ice Crystals (*Review*), 778, Crystals, W A Bentley and W J Humphreys (*Review*), 778
- Soap Plants, H Friend, 52, Solutions, Surface Tension of, Dr P Lecomte du Nouy, 278
- Social Economics (*Review*), 558, Service, Knowledge and, 73
- Society Islands' Canoes, Dr E S C Handy, 692
- Society, Science and, Prof F S Marvin (*Review*), 329
- Sodium Hydrosulphide, Some Analytical Applications of, B S Evans, 518
- Soil and the Microbe, The, an Introduction to the Study of the Microscopic Population of the Soil and its Role in Soil Processes and Plant Growth, Prof S A Waksman and Prof R L Starkey (*Review*), 600, Conditions and Plant Growth, Sir E John Russell Sixth edition (*Review*), 527, Formation in South-West England, Climate and Parent Material in, A J Low, 655, Physics and Chemistry of the, Prof H A D Neville (*Review*), 706, in Relation to Meteorology, Dr B A Keen (G J Symons Memorial Lecture), 463, The, an Introduction to the Scientific Study of the Growth of Crops, Sir A D Hall Fourth edition (*Review*), 706, The Study of the, Prof E J Salisbury (*Review*), 527
- Soils, Weathering of, Degree of, Prof G W Robinson and Dr Minnie Richardson, 581
- Solar and Terrestrial Relationships, 405, Corona Photography of the, apart from Eclipses, B Lyot, 141, Study of the, with the Spectro-heliograph otherwise than during an Eclipse, B Lyot, 447, Eclipse of Aug 31, 1932, Suggested Wireless Observations during the, Prof E V Appleton and Prof S Chapman, 757, System, The Origin of the, Prof H Dingle, 333
- Solution of Gas in a Liquid, Rates of, Miyamoto, 693
- Somaliland, British Climatic Changes in, Dr J Parkinson, 651, Freshwater and Land Mollusca from, Dr J Parkinson, 941
- Somerset, The Archaeology of, D P Dobson (*Review*), 924
- Sorcerers of Dobu the Social Anthropology of the Dobu Islanders of the Western Pacific, Dr R F Fortune (*Review*), 669
- Sorghum* Chromosomes of, Prof C L Huskins and Stanley G Smith, 835, Sudan Grass and some Hybrids, The Amount of Hydrocyanic Acid in, H Finmore and C B Cox, 35
- Sound -Change and Indeterminism, A S C Ross, 760, Films Application of, to Timing Solar Eclipses, 549; in Schools, 174, Reproduction, Discs and Conical Diaphragms in, Dr N W McLachlan, 549
- South Africa Botanic Gardens in, Sir Arthur W Hill, 343, Prehistoric Stock of, Sir Arthur Keith, 90, African Grasses An Introduction to the Study of the, with Notes on their Structure, Distribution, Cultivation, etc, Dr E P Phillips (*Review*), 382, -Eastern Union of Scientific Societies, Congress of the, Prof E J Salisbury elected President for 1933, 875, Sandwich Islands, Dr S Kemp and A L Nelson, with a Report on Rock Specimens, by Dr G W Tyrrell, 731, -West Museum, Los Angeles, F Hodge appointed director of the, 20
- Southern Ocean, Mapping of the, 283
- Soviet Academy of Science, Expeditions of the, 754
- Space-Time Continuum, Dr F H Maberly, 317
- Spanish-African Fever, The Individual Specificity of the Spirochaetes of Recurring, C Nicolle and C Anderson, 951
- Species Hybridisation in Animals, R I Pocock, 394
- Specificity in Catalysis, Sir Frederick Gowland Hopkins (Robert Boyle Lecture), 322
- Spectroscopy and Valency, C H D Clark (1), 734
- Speed Records, New Land, Sir Malcolm Campbell, 342
- Spencer's Last Journey being the Journal of an Expedition to Tierra del Fuego by the late Sir Baldwin Spencer with a Memoir Edited by R R Marett and T K Penniman With Contributions by Sir James Frazer and H Balfour (*Review*), 43
- Spinels, Researches on, L Passerini and M Baccaredda (4), 142
- Spiral Nebulae Two very Distant, 284, Velocities of the, Prof W D MacMillan, 93
- Spurifer*, Genus, Studies of Evolution in the, C L Fenton (*Review*), 383
- Spirochaeta hispanicum*, Sensibility of the Pig to African Strains of, C Nicolle and C Anderson, 410
- Spirula* from the Dana Expeditions, Prof Graham Kerr, 403

- Verres, émaux, céramiques, Décoration des, Prof Suzanne Zaborowska (*Review*), 8
- Vertebral Column, Development of the, Prof E W MacBride, 872
- Vertebraria, Structure of, J Walton and Jessie A R Wilson, 626
- Vertebrates, Comparative Anatomy of, H W Rand (*Review*), 780
- Vertical Tube Counter- and the Barometric-Effect of Cosmic Radiation at Sea-level, Prof W Kolhorster, 471
- Vesuvius, The Magma of, Dr A Rittmann, 873
- Veterinary Research in South Africa, Prof P J du Toit, 232
- Vibrating Electrons in Ionised Air, Collisional Friction experienced by, Prof E V Appleton and F W Chapman, 553
- Vibration of Truncated Conical Shells, The Symmetrical Modes of, with Applications to Loud-Speaker Diaphragms, Dr N W McLachlan, 769
- Vibrations of a Lofty Building, T Fukutomi, 693
- Vibrato, Natural History of the, C E Seasnore, 591
- Vicia Faba, Perception of Gravity by Roots of, Lilian E Hawker, 364
- Villages et Kasbas berberes tableaux de la vie sociale des Berbères sédentaires dans le sud du Maroc, R Montagne (*Review*), 80
- Vimaria denudata, Reaction of, to increased Water Content of the Soil, Lilian Fraser, 255
- Vine Leaves, Effects of Tartaric Acid and of Glucose on the Metabolism of, E T Everingham and Dr W H Pearsall, 214
- Viruses, Filterable, Problems of, 48
- Viscosity and its Relation to Temperature, R M Deeley, 125, of Liquids, Prof E N da C Andrade, 125, of Mixtures of Stannic Chloride with Aromatic Hydrocarbons, F De Carli, 215
- Visibility at Sea, W H Pick, 410, with Saturated Air, W H Pick, 68
- Vision Central and Peripheral, Dr F W Edridge-Green, 943, Discussion on, 947
- Visual Acuity on Illumination, Basis of the Dependence of, W W Wilcox, 735, Thresholds, Influence of Coloured Surrounds and Coloured Backgrounds on, Prof H E Roaf, 733
- Vitamin. A Halibut Liver Oil as a Source of, J A Lovern, 726, Isolation of, Prof P Karrer, R Morf, and K Schopp, Prof J C Drummond, Prof I M Heilbron, and Dr R A Morton, 88, Assays, Quantitative Methods in, 514, B and Phytase, Cuboni and Arnaud, 101, Isolation of, Prof Windaus and others, 161, C, Origin of, O Rygh, A Rygh, and P Laland, 283, D and Related Compounds, Crystal Structures of, J D Bernal, 277, Crystalline F A Askew, R B Boudillon, H M Bruce, R K Callow, J St L Philpot, and T A Webster, 178, Commercial, British Drug Houses, Ltd, 17, Effect of an Insufficient Supply of, on the Growth of the Skeletons and Internal Organs of Chickens, E J Sheehy, 106, Synthesis of, C E Bills and F G McDonald, 50
- Vitamins A, B, C, D, Photochemistry of, Dr F P Bowden and Dr C P Snow, 720, 943, Prof I M Heilbron and Dr R A Morton, 866, Crystalline, Properties and Structures of, J D Bernal, 721
- Voltage, Absolute Measurement of, Prof W M Thornton and W G Thompson, 208
- Vortex in a Field limited by a Cardioid, B Caldonazzo, 69, Motion in Vibrating Columns of Air, Prof E N da C Andrade, 711
- Viscosity and Heat, The Transport of, through Fluids in Turbulent Motion, Prof G I Taylor, 409
- Walder Ökologie des, mit besonderer Berücksichtigung des deutschen Wirtschaftswaldes, Prof A Dengler (*Review*), 631
- Wallach, Otto, The Life and Work of, Prof J (Pedler), 428

- Wings over Europe, R Nicholas and M Brown, 680
- Winter in the Ionosphere, R A Watson Watt, 761
- Wireless a Treatise on the Theory and Practice of High-Frequency Electric Signalling, L B Turner (*Review*), 595, Observations, Suggested, during the Solar Eclipse of August 31, 1932, Prof E V Appleton and Prof S Chapman, 757, Principles, The Study of, Dr R L Smith-Rose (*Review*), 595, Waves, Downcoming, Polarisation of, J A Ratchiffe and F W G White, 364, World, twenty-first birthday of the, 716
- Witchcraft on the Gold Coast, 464
- Witches in West Africa, Challenge to, Bishop of Accra, 862
- Witwatersrand Gold, Origin of, 62, University, Fire at, 20, The Library of, 717
- Wolf-Rayet Stars, Temperatures of the, V Ambarzumian, 725
- Wood -boring... Structural Timber, Method of determining... Penetration of, J B Butler, 553, in the Tropics, C J H... The Phloroglucinol... of Mechanical, H B... The Shrinkage of,

- World Chaos the Responsibility of Science, Prof W McDougall (*Review*), 295, Order, Towards a New (*Review*), 882
- Worm-Lions, Ant-Lions and, Prof J S Gardiner (*Review*), 39
- Xenopus laevis*, Adrenal Gland of, H Zwarenstein and I Schrire, 914
- X-Ray Absorption, *L*-Discontinuities in, E Olsson, 94, Characteristic Spectra, Complex, Prof M N Saha, Saligram Bhargava, and J B Mukerji, 435, Crystal Analysis and its Applications, Sir William Bragg, 610, Lines, Fluorescent, Intensity Ratio of, Prof G Hevesy and E Alexander, 315, *L*-Levels, Relative Excitation of the Three, with Cathode Rays of Different Velocities, Prof D Coster and J van Zuylen, 942, Spectra, Quadruple Lines in, E Segrè, 627, Standards, Dr L S Taylor, 908, Wave-lengths J A Bearden, 404, Absolute Values of, and the Fundamental Atomic Constants, Prof M Siegbahn and M Soderman, 21
- X-Rays Discovery and Uses of, 271, Reflection of, Intensity of, by Perfect Crystals, G W Brindley, 213, Refraction of, by Perfect Crystals, G W Brindley, 733
- Yagé, a South American Drug Plant, C V Morton, 247
- Yeasts, Nutrition of the, F Chodat and J Landis, 771
- Yellow Fever, Vaccination of Man against, A W Sellards and J Laigret, 915
- Young, Champollion, and Hieroglyphics, Dr A Ferguson, 638
- Yuma Ethnography, Prof C D Forde, 318
- Yurok-Karok Basket Weavers, Miss Lila M O'Neale, 727
- Zebra-fish, Feeding Habits of the, C M Breder, 763
- Zebu-Yak Hybrids, M M Zavadovsky, 727
- Zeeman Effect, *e/m* from the, J. S Campbell and W V Houston, 693
- Zeolites, Studies on the (3), M H Hey, 410
- Zinc and Cadmium, Comparison of the Electrolytic Deposits of, H Figour and P Jacquet, 879, and Manganese, Alloys of, N Parravano and V Caghoti, 375
- $\beta$ -Zirconium, Crystal Structure of, Dr W G Burgers, 281
- Zodiacal Light, The, and the Luminosity of the Night Sky, Dr K R Ramanathan, 280
- Zoological Society's Gardens, The Haapy at the, 826, Survey of India, The, Lieut-Col R B Seymour Sewell, 530
- Zoologie, Allgemeines, Grundriss der, Prof A Kuhn Vierte Auflage (*Review*), 925
- Zwischenstufen, Die sexuellen, Prof R Goldschmidt (*Review*), 3
- Zytologie, Einführung in die, Prof L W Sharp Mit Genehmigung des Verfassers aus dem Englischen übersetzt und vollständig neu bearbeitet von Prof, R Jaretsky (*Review*), 600

The various Supplements should be collated and bound with the numbers with which they were issued.

## A WEEKLY JOURNAL OF SCIENCE

*"To the solid ground  
Of Nature trusts the mind that builds for aye"*—WORDSWORTH.

SATURDAY, JANUARY 2, 1932.

### CONTENTS.

|                                                                                                                             | PAGE |
|-----------------------------------------------------------------------------------------------------------------------------|------|
| Science and Imperial Affairs                                                                                                | 1    |
| Hermaphrodites                                                                                                              | 3    |
| Comparative Psychology in the Field By J A T                                                                                | 6    |
| The Science of Oceanography By F S Russell                                                                                  | 7    |
| Short Reviews                                                                                                               | 8    |
| Scientific Centenaries in 1932                                                                                              | 10   |

### Science and Imperial Affairs.

SINCE the War, both Houses of Parliament and those members of the general public interested in Imperial matters have devoted more attention to the affairs of the five countries under British control in East Africa than to any other part of the British Empire except India. Numerous white papers on East Africa have been presented to Parliament in 1924 a special East Africa Committee was appointed, on which all three political parties and other interests were represented in the same year Mr Ormsby-Gore, Major Church, and Mr Linfield made a tour of the five countries and presented a long report to Parliament in 1925 in 1927 a further commission, to consider the possibility of the closer union of the territories, was sent out under the chairmanship of Sir Hilton Young. Following the publication of the still more voluminous report of that visiting commission, the Permanent Under-Secretary of State for the Colonies, Sir Samuel Wilson, proceeded to East Africa himself to discuss the recommendations of the Hilton Young Commission with the Colonial Governments concerned, and his report was presented to Parliament in July 1929. In June 1930, Lord Passfield, then Secretary of State for the Colonies, issued a "Statement of the Conclusions of His Majesty's Government in the United Kingdom as regards Closer Union in East Africa", and a memorandum on native policy and finally Parliament appointed a Joint Committee of both Houses to consider the Reports on Closer Union in East Africa and other relevant documents. The report of that joint committee was recently presented to Parliament.

The reports of the Ormsby-Gore and Hilton Young Commissions were the subject of editorial comment in *NATURE* at the respective times of their presentation to Parliament. The Ormsby-Gore Commission, which was primarily concerned with the economic development of East Africa, quite properly dealt with political questions only in relation to their effect on such development. It was a report in striking contrast with previous reports on Colonial matters because of the exceptional prominence it gave to the dependence of economic progress on the generous provision of education and medical services, the adequate provision of scientific and technical services, and the prosecution of scientific research in connexion with social as well as <sup>purely</sup> economic problems. It directed attention to the regrettable abandonment by the East African Governments of the once famous Amani Plant Research Institute, to the need for the creation of a central veterinary research station, to serve the five territories, the establishment and endowment of a central research institute for the investigation of human tripanosomiasis (sleeping sickness), the inauguration of a great campaign against tsetse flies directed by qualified scientific experts, the re-establishment of a geological survey department in Tanganyika and the establishment of a similar department in Kenya, the organisation of anthropological research, the more energetic prosecution of plant and animal breeding experiments by the various departments of agriculture, and a scientific and comprehensive survey of the lake and marine fisheries of East Africa.

That practically all the recommendations of the Ormsby-Gore Commission in connexion with these matters were acted upon within two years was due to the energy and enthusiasm with which Mr. Ormsby-Gore and Major Church applied themselves to the task of stirring the authorities at home and in the Colonies to the need for immediate action. The fact that neither the Hilton Young Commission nor the Joint Select Committee on East Africa has found it necessary to add any further suggestions for the furtherance of scientific research is eloquent testimony to the thoroughness of their original survey.

It must be confessed, however, that the various bodies representing the interests of science in Great Britain displayed a lamentable lack of appreciation of the fact that the Ormsby-Gore report provided them with an unusual opportunity to participate more energetically in framing an Imperial policy. At that time they could have

made statesmen and politicians realise that the scientific community ought not merely to be consulted by, but represented on, any and every committee set up by Government to consider any aspect of economic development at home or overseas. Incidentally, what is equally important, they could have insisted on their competence to appoint their representatives themselves, and not, as is the custom on those rare occasions when the Government does appoint a man of science on a committee, to have their representatives chosen for them by Government officials.

Since the scientific community in general has taken so little interest in the prosecution of research and the provision of essential scientific services in the Colonies, it is not surprising that successive Governments have ignored them when appointing committees to consider Colonial services and development. There is no representative of science on the Empire Marketing Board, and until recently there was no member of the scientific community on the Research Grants Committee of that body. The scientific interest was not represented on the Committee appointed in 1925 under Sir George Schuster to consider the allocation of the East Africa Development Loan which was recommended by the Ormsby-Gore Commission, although this Committee was dealing with grants for the establishment of research institutions and for *ad hoc* researches. The Hilton Young Commission of 1927, the terms of reference of which included the co-ordination of the scientific and technical services in East Africa, contained no scientific member, although the missionary societies were represented. The Labour Government ignored the scientific community in appointing members of the Colonial Development Advisory Committee, although this Committee had to consider schemes for the provision of scientific research. It is worthy of note also that the Labour Government, which appointed the Joint Select Committee of both Houses of Parliament on Closer Union in East Africa, deliberately excluded Major Church, its only representative in the Commons who had first-hand acquaintance with the territories under review, whose main contributions to the report of the Ormsby-Gore Commission had been the chapters dealing with medical and scientific research, and who could claim to represent scientific interests in Parliament.

The above list of Committees, appointed by various Governments during the past eight years, on which the scientific community should have been, but was not, represented, is by no means

exhaustive. It is long enough, however, to establish the fact that Governments will ignore scientific workers while the latter remain indifferent to the affairs of State, more indifferent, it appears, than any other section of the community, although statecraft is now mainly a question of making humanity fit for science, or at least of modifying the political and economic systems of the world to enable its inhabitants to enjoy the fruits of scientific endeavour.

That the scientific community is indifferent is borne out by the fact that on no occasion has it combined to protest publicly against the omission of its representatives from any of the important bodies enumerated above, all appointed to deal with subjects to which men of science could make important contributions, more authoritative and carrying far more conviction than if made by others with merely a vicarious interest in their work, and usually unable to appreciate the fact that the scientific outlook is even more important in dealing with Imperial or world problems than the mere application of the results of science to productive processes.

The question arises, however, are there many scientific workers themselves who are conscious of the significance of a scientific outlook as distinct from a scientific result? If there were many such, would it not be reasonable to assume that they would recognise this 'outlook' as the integrating force and create a unified representative body for the whole mass of scientific practitioners and believers in science in the British Empire? Such a body is obviously necessary if nations are to be encouraged to think scientifically. Unfortunately, the tendency towards specialisation, inevitable and of paramount importance for the advancement of scientific knowledge, has obscured the essential unity and the grander purpose of those trained in the sciences. This unity can be attained if the many specialist scientific and technical societies and institutions will recognise their limitations, and that as discrete fragments of the world of science they cannot hope to fulfil the nobler aim. They must join forces and create a strong body that can, a body the primary function of which is to inculcate a scientific outlook and promote the application of scientific method and results to national and Imperial affairs. This, in fact, is the avowed function of the British Science Guild, and there is little doubt that, with adequate support from the specialist scientific societies, such a body could get the respect for science which science deserves, and secure for science that representation in the councils of the nation which the nation and the Empire urgently need.

### Hermaphrodites.

*Die sexuellen Zwischenstufen* Von Prof Dr Richard Goldschmidt (Monographien aus dem Gesamtgebiet der Physiologie der Pflanzen und der Tiere, Band 23) Pp x+528 (Berlin Julius Springer, 1931) 46 40 gold marks

IT is now eleven years since Dr Goldschmidt brought out the well-known volume of which an English translation appeared in 1923 as "The Mechanism and Physiology of Sex-Determination". The present work elaborates that section of his former book, which treated of what are generally termed hermaphrodites, a proper understanding of which is so essential to a full appreciation of the nature of sex itself. To that understanding no one has contributed more than the author, for it was through his remarkable researches on the races of the gipsy moth (*Lymantria dispar*) that the problem of the intersex has crystallised out of that vast conglomerate of miscellaneous knowledge comprised under the heading of sex.

Goldschmidt's interpretation of the phenomena with which he deals is, of course, based upon the fact that sex, like any other hereditary character, is normally determined by specific genes which are definitely located in the chromosomal material. Where the sexes are separate the difference between them is determined by a single gene, or by a gene complex behaving normally as one, whence it follows that in the ordinary way the sexes are produced in approximately equal proportions. Such equality may be upset in various ways—for example, by differences in viability at various stages in development, by the association of a lethal factor with one sex or the other, and by other means. In such cases, however, in spite of the upsetting of the numerical balance between the sexes, their physiological distinctness remains unaffected, and the ultimate result is normal males and normal females.

Such a scheme, based on the ordinary conceptions of Mendelian heredity, offers a satisfactory explanation of most of the phenomena connected with the inheritance of sex. But it does not explain the hermaphrodite. As already stated, attention was first focused on this problem by Goldschmidt's work with the gipsy moth, a species in which the form and colour of the female is very distinct from that of the male. An amateur breeder, Herr Brake, pointed out that in certain crosses between the European gipsy moth (*L. dispar*) and a form from Japan (var *japonica*) there appeared forms more or less intermediate in sex characters. He called them gynandromorphs, and for some years

found a ready sale for them among those who collect Lepidoptera in the spirit in which others collect postage stamps. In 1910 Goldschmidt started his remarkable analysis of the case—an analysis spread over twenty years and involving visits to Japan in connexion with the determination and crossing of the geographical races, morphological and physiological investigations, and the critical breeding of tens of thousands of moths. The gist of his interpretation is as follows.

As in other Lepidoptera, the male is the homogametic sex with two sex chromosomes carrying a sex factor, the female carrying but one. In other words, the male is homozygous for a factor,  $M$ , which stimulates the male part of the genital complex, while the female is only heterozygous for this factor. In the cytoplasm, on the other hand, is something which stimulates the production of the female part of the genital complex. This substance ( $F$ ), being cytoplasmic, is maternally transmitted, and all the offspring receive an  $F$  of the same quality as that of their mother. In an ordinary race, such as the European *dispar*, the genetical constitution of a male is  $FMM$ , and that of a female  $FM$ . The female-producing tendency of the cytoplasmic  $F$  can be overcome by two 'doses' of  $M$ , but not by one dose. Hence the production of normal males and females in equal numbers, and of normal males and females only, and this is true for each given pure race of *Lymantria*. The explanation of the appearance of intersexes on crossing different races turns upon the assumption that the intensity of the action of  $F$  and  $M$  differs in the different races. Thus in *japonica* both  $F$  and  $M$  are 'stronger' than in *dispar*, that is, they exert their influence earlier in the course of development; conveniently they may be denoted as  $F_s$  and  $M_s$  to distinguish them from the  $F$  and  $M$  of *dispar*. The cross between *dispar* female ( $FM$ ) and *japonica* male ( $F_sM_sM_s$ ) results in two kinds of individuals of the constitution  $FMM_s$  and  $FM_s$ , respectively. The former are normal males in appearance, but the latter are intersexes. For the 'strong' male factor ( $M_s$ ) from *japonica* partly overrides the female-producing cytoplasm ( $F$ ) from the 'weaker' parent which is inherited maternally by all the offspring from this cross. From the reciprocal cross, *japonica* ♀ ( $F_sM_s$ ) × *dispar* ♂ ( $FMM$ ) only apparently normal ♂♂ ( $F_sM_sM$ ) and normal ♀♀ ( $F_sM$ ) are produced. For a weak ( $M$ ) and a strong ( $M_s$ ) male factor together can override the strong cytoplasm ( $F_s$ ). But in  $F_2$  from this cross appears the fresh combination  $F_sMM$ , which must be regarded as the genetical constitution

of the so-called male intersexes that appear in this generation. For two doses of the weak  $M$  cannot completely override the strong  $F_s$ .

When in Japan, Goldschmidt distinguished eight races of *Lymantria*, and an elaborate series\* of breeding experiments enabled him to arrange them in a series of decreasing 'strength'. The difference between the extremes of this series was greater than between European *dispar* and the Japanese race used in the earlier work. Indeed, it was so great that when the weakest was used as the mother and the strongest as the father, males alone resulted. Subsequent experiment showed that while about half of these males were chromosomally males ( $FM_sM_s$ ), the rest were really females ( $FM_s$ ) in which the male factor ( $M_s$ ), introduced from the strong race, was so strong as to override entirely the cytoplasmic  $F$  of the weaker, and to cause a complete reversal of the sex as judged by chromosomal constitution. Conversely, Goldschmidt was also able to obtain from these two races insects of the constitution  $F_sMM$ , individuals chromosomally males but in appearance females owing to the complete overriding of the weak  $M$  by the strong  $F_s$ . Through crosses between the different races every grade of intersex could be obtained, but with given races the grades could be predicted even in highly complex crosses. Although the 'strength' or 'valency' of the sex factor differed for each race, it was in each race fixed, and Goldschmidt suggests that this fixity is at bottom quantitative, depending upon definite amounts of the sex-determining material present in any case. He supports his views by reference to the triploid intersexes in *Drosophila*, which cytological work has shown to depend upon the relative proportion of X chromosomes and autosomes.

In these cases among insects, to which may perhaps be added a few more among other invertebrates, the intersexuality depends upon the constitution of the zygote as determined at fertilisation. Goldschmidt then proceeds to consider a group of cases, also among arthropods, where parasitic infection by another arthropod may lead to partial, or even complete, reversal of sex, and he argues that this group of cases may also be brought into line with the conceptions derived from the *Lymantria* case. Perhaps the best known of this group is that of the crabs, in which infection by the rhizocephalan *Sacculina* leads to the male assuming in varying degree the female type of abdomen and appendages, and even developing ovarian tissue after the loss of the parasite. Goldschmidt suggests that the action of the parasite may be to upset the

normal balance between the *F* and *M* substances, either by destroying one or by increasing the other. There is, however, a peculiarity about this group of cases in that, with the possible exception of the stylipised *Andraena*, the intersex is always the result of the male becoming more or less feminised. Such changes as occur in the female may be regarded as merely an arrest in the normal development. The case for what may be called 'reciprocal reversal' rests upon the colour changes in the clypeus of *Andraena* in different species, and one would like to know more about the genetics of this character before accepting Goldschmidt's view.

The so-called parasitic castration group shows, however, that the sexual characters inherent in the zygotic constitution of the individual may be largely modified by influences extraneous to the cell. This is of course markedly the case for the vertebrates, where the development of sexual characters is largely dependent upon the hormones or internal secretions developed by the gonad, and by other glands as well. The wide difference in this respect between arthropods and vertebrates is well shown by castration experiments. In *Lymantria*, as Meisenheimer showed many years ago, castration in the larval stage, whether simple or followed by transplantation of the gonad of the opposite sex, has no effect either on the sexual apparatus or on the secondary sexual characters. The turning-point is already past and the sex irrevocably determined before the operation has become a practical possibility. In vertebrates, however, as is well known, castration produces marked changes, the magnitude of which is to some extent dependent upon the stage at which the operation is performed. In general, it may be said not only to arrest the development of the sexual apparatus itself, but also to inhibit in many cases the appearance of secondary sexual characters. The normal condition may, however, be restored by implantation of a gonad of the same sex. Even more remarkable is the result of implanting a gonad of the opposite sex, for in this way a female may be caused to develop many of the characters of the male, and vice versa.

Goldschmidt's book provides an excellent and critical account of all the more important work that has been done along these lines. He points out, too, that although the sexual complex in vertebrates is so sensitive to hormonal secretions, we can nevertheless distinguish certain cases in which an intersexual condition must be regarded as directly dependent upon the zygotic constitution of the individual. The clearest cases are in the goat and the pig, particularly that of the remarkable New

Hebridean swine described by Baker, and Goldschmidt is justified in pointing out the parallel which they afford to his *Lymantrias*. For there can be little doubt that here also the peculiarities are hereditary, and due primarily to zygotic constitution. A valuable feature in Goldschmidt's book is his review of intersexuality in man, a subject hitherto much confused by the speculations of medical men who lack genetical training. Though most of the phenomena can be brought into line with those exhibited by the pig and the goat, there are certain others that are very puzzling. Among these are gynæcomasty and homosexuality, and Goldschmidt is inclined to look for an explanation in a defect of some endocrine secretion rather than in zygotic constitution, the criterion of intersexuality proper.

The last part of the book is devoted to a consideration of gynandromorphs as distinct from intersexes. This important distinction we owe to the author himself, who once aptly described the former as hermaphrodites in space and the latter as hermaphrodites in time. For, whereas the latter are sex compromises dependent upon the relative speeds at which the *M* and *F* substances get to work, the former are merely mosaics of purely male and purely female tissues. The formation of such a mosaic generally depends upon the elimination of a sex chromosome at some stage or other in cell division. Thus, if a fertilised *XX* egg of *Drosophila*, which would normally develop into a female, drops out an *X* from one of the two cells resulting from the first division, and if then development proceeds normally, one half of the resulting insect will be *XX* and the other half *X* in constitution. Hence one half of the body will be female and the other half male, that is, the insect will be a bilateral gynandromorph. But polyspermy or binucleate eggs may also be sources of gynandromorphs, and the reader will find a clear exposition of the various possibilities. Of great interest, too, is the account of the hereditary nature of gynandromorphs in the silkworm, the working out of which we owe to the author.

Taking it altogether, the book gives what is undoubtedly the fullest and most lucid exposition of the subject that at present exists. On some points the reader may disagree with the author's views, but the position of those with whom he may not hold is always fairly met, however sharply criticised. As befits a master of his subject, the dominant idea throughout is synthesis, the attempt to weave into a coherent whole a great mass of facts, using *Lymantria* as the guiding thread. The result is a

valuable and highly stimulating book, admirably documented on an excellent bibliography. On one point alone is it possible to quarrel with it. For, though well produced and fully illustrated, the price appears to us to be exorbitant. One can only hope that this will not restrict the sale of a work that in the interests of knowledge deserves a wide circulation.

### Comparative Psychology in the Field.

*The Intelligence of Animals. Studies in Comparative Psychology.* By Frances Pitt. Pp 320 + 46 plates (London: George Allen and Unwin, Ltd., 1931) 15s net.

FOR many years Miss Frances Pitt's books have adorned the front rank of observational studies in animal behaviour. One was always sure of finding fresh material, as reliable as it was interesting. Gradually, however, the gifted observer has become more frankly reflective, as in her "Animal Mind", and now we have a record in which the inferences are definite contributions towards a solution of some of the deeper problems of biology. The outcome is a psycho-biological picture, convincing us afresh that we cannot describe the ways of animals, or account for their survival, unless we do justice to their 'mentality', including in that term all the creature's mental acquirements, characteristics, and predispositions. That intelligence and parental affection may have survival value will be admitted by most open-air naturalists, but Miss Pitt shows that we must also take account of subtler qualities, such as tameness and confidingness, wariness and shyness, a desire to be left alone, and a liking for neighbours. Inferences cannot, of course, claim the cogency of observations, but Miss Pitt states a strong case for the validity of psycho-biology, stressing the mind-body as much as the body-mind. Even temperament may have survival value in wild Nature.

The first studies have to do with call or decoy ducks, a domesticated race of mallards, which show how the 'wild' may give rise to the 'tame' and lose some of its most characteristic features, such as monogamous and migratory habits. The wild mallard is not turned into the tame decoy, but a selection of stay-at-home individuals, sustained for generations, results in the elimination of the wandering and migratory impulse. The tame type is in most cases quite content to stay all the year round upon two or three small pools, despite the fact that it has wings at its command and might wander far if it pleased. "The strict monogamy

that characterises the mallard suffers in the case of the decoy duck from the deteriorating influences of man and domestication." The duck remains faithful, but the drake generally makes use of his opportunities to 'transgress'—a term which is not, of course, meant to imply an avian code of morals in the strict sense.

In the second set of studies, centred in the semi-domesticated peafowl, Miss Pitt has many observations of great interest. It looks as if the peacock's display is in the main an expression of exuberant sex-excitement. He may show off to ducks, the hen is often bored by the display, there is little to suggest that the cock has any inkling of his own splendour. As the display involves considerable strain, as in rattling the quills, we search for some other utility if we abandon (as we are not yet prepared to do) the theory that it infectiously rouses the interest and sex-excitement of the hen. Miss Pitt interprets its biological function as "probably that of advertisement, so that the female may know the whereabouts of the male, and especially her male." For the hens are faithful to their chosen polygynous cock.

Very important, as it seems to us, is the conclusion that the showing-off attitude, with erection of the tail-coverts, is the same in the tiny chicks, in the young birds of both sexes, in the old hens, and in the adult males. "Under stress of emotion they all behave in the same manner." In other words, the sex-urge utilises and emphasises a general gesture. Chicks not ten days old, excited by the sudden appearance of a pet raven, erected their diminutive tail-coverts just as did their strutting sire.

Another observation on young peafowl is very interesting: that when they lost their mother, about three weeks after hatching, and were pining, they took courage when the hurriedly stuffed body was brought on the scene, and behaved to it, doubtless on the strength of established associations, exactly as if the mummy, which became flat and loathsome, were actually alive. There are many similar treasures in this delightful and reliable book, but we cannot do more than indicate the general nature of the observations.

The third part of the book deals with the horse, cow, sheep, and pig, and readers of Miss Pitt's "Animal Mind" will not be surprised that her estimate of the horse's mentality is lower than that usually approved, while her estimate of the other three ungulates is higher. Scientific and impersonal as we try to be, we cannot, while comparative psychology remains relatively inexact, readily get away from our individual experience of individual

animals Thus we personally think that the horse's intelligence is much greater than Miss Pitt can see her way to allow

The fourth section of the book is devoted to dog and cat, and it pricks some bubbles of reputation We breathe more freely when we discover that the dog still remains worthy of being called intelligent, while the cat's mind is left as an elusive mystery behind its inscrutable green eyes

The fifth part deals with the fox, as a type of the thoroughly wild mammal As a sample of the careful phrasing that marks the whole book, we quote Miss Pitt's verdict on the fox

"My opinion of the average fox is that it ranks high in the scale of intelligent mammals, but that much of its conduct is regulated by inherited response, though such instinctive aptitude is ever qualified by experience, by which the fox profits to a marked degree, its very educability proving its intelligence If not so super-intelligent as some sporting writers and the sentimental story-writers would have us believe, it is equally far removed from the thing of merely automatic responses that the behaviourist school make of our mammals"

This is well and wisely said, yet perhaps there is something to be gained by keeping the word 'conduct' for those rationally or ethically controlled human activities which rise above 'behaviour'

The sixth section is perhaps the subtlest in the book, and thus the least convincing It takes lemming, crane, and Skomer vole as illustrations of the thesis that temperament has survival value in the struggle for existence The lemming's behaviour is characterised by the temperamental quality we call tameness, which is made possible by certain compensatory advantages, such as the habit of burrowing beneath the enveloping mantle of snow and the capacity for very prolific multiplication The apparently contradictory intimidating display in a tight corner is the outcome of a mixed emotion of fear and anger It is a useless and often risky form of 'bluff'

Why is this delightful book of high scientific value? Because it is a vindication of the importance of the mental factor in determining the status of an animal, its survival and distribution—a vindication by an expert observer who is aware of the many pitfalls of psycho-biological interpretation We quote her concluding sentence

"Every bird, beast, and lower creature supplies us with a problem of the highest interest—namely, the elucidation of the factors that control its position in the web of life, of which factors those governing behaviour are the most vital, especially the mind that governs purposive action"

## The Science of Oceanography.

*Oceanography its Scope, Problems, and Economic Importance* By Henry B Bigelow Pp vii + 263 (Boston and New York Houghton Mifflin Co., London Chapman and Hall, Ltd., 1931) 12s 6d net

IT is barely sixty years since H M S *Challenger*, by her exploratory voyages round the world, built the foundations upon which the modern science of oceanography has grown up For centuries man had roamed the seas and charted their boundaries, looking for new land or trade routes rather than for a knowledge of the sea itself Exploration showed that less than one-third of the earth's surface is dry land, now that most of this has been mapped, attention is being turned more and more to the remaining two-thirds, which forms a world of its own, and by the very reason of its vastness holds the key to many of the secrets of land phenomena.

The geologist must look to the nature of the ocean bed for help in the solution of some of the most pressing questions in the study of the earth's crust This involves a knowledge of the sediments now being deposited on the sea floor, of the rate of their deposition, and the question of their subsequent solution These phenomena are so intimately bound up with the physics, chemistry, and biology of the sea that they emphasise at once the unity of oceanographical science The presentation of the whole story of the course of events at the present day would throw much light on the past history of our sedimentary rocks The study of dynamic geology further demands a more complete knowledge of the contours of the great ocean beds, combined with gravity measurements to determine the density of the earth's crust

To the biologist the sea represents a world in itself, in fact, once the excitement of research on life in the sea has gripped the beginner, he is liable to forget that a zoology of animals on dry land exists This is pardonable, when it is realised that there are probably few problems on land that have not their parallels in the sea, in which all life was evolved Owing to the peculiarity of the environment also, the very fundamentals of life appear to be best open to attack, for it is in the sea that life is at its simplest and the living organism is least cut off from its surrounding medium by the development of protecting structures It is for this reason, perhaps, that the marine biologist at once feels that any observations he makes are sadly lacking if he does not possess the necessary physical and chemical

data of the environment. For the sea is a whole, and must be treated as such for a correct understanding of the manifold problems that surround us. Where the whole water mass is in constant circulation, changes in one locality may be far-reaching and make their effects felt in the remotest regions. Perhaps nowhere is this more obvious than in the study of the great fluctuations in marine life, the ultimate effects of which are brought home to us in the fisheries from which we draw so much of our food supply.

We have travelled a short way only along the road of oceanography, but everywhere the signposts point to the need for networks of fuller and more complete observations over wide spaces and over long periods of time. Such need is, perhaps, most outstanding in the realm of physical and chemical oceanography, where the actual movements of the water masses are concerned, movements which, apart from their enormous biological implications, must have a bearing on meteorology and on navigation. It awaits to be shown whether correlation can be found between the conditions of water masses in one region and later meteorological conditions in far distant localities, a problem that alone involves many years of labour. But if such correlation should be found, its great economic value in the possibilities of long range weather forecasting is obvious to all.

Oceanographical investigation is expensive, entailing as it must do the running of a well-found ship. The solution of many of the most pressing problems is not insurmountable with mechanics to our aid, and here again the building and elaboration of effective apparatus is always expensive. For these reasons, with few exceptions, most schemes of research have been State-aided, and apart from the great exploratory voyages, the ultimate assistance of the fishing industries or the safeguarding of navigation have been held up as the main ends in view.

Last summer, however, one of the finest private marine institutions opened its doors at Woods Hole, alongside the two well-known existing laboratories. As a true marine laboratory, it has as its object the advancement of any knowledge that can be gained from an investigation of the sea. Operating from the laboratory is an ocean-going research vessel, the *Atlantis*, which has already completed her maiden voyage across the North Atlantic Ocean. The institution, which has been fully endowed by the Rockefeller Trust, is thus in a position to carry out a continuous study of the sea unhampered by the desire for immediate econ-

omic return for knowledge gained. The Director of the Woods Hole Oceanographical Institution, Prof. Henry B. Bigelow, has brought together in a masterly manner the present position of oceanographical research and its implications. One may conjecture that this report, which was laid before the National Academy of Sciences, was in no small degree responsible for the birth of the Woods Hole Institute. In the author's words, the book "is in no sense a text-book or a compendium of oceanographic knowledge." It does, however, very adequately lay before us some of the many problems still awaiting investigation in the science of oceanography, and as such deserves to be read by the research worker and the student.

F. S. RUSSELL

### Short Reviews.

- (1) *Dorure-encadrement technique des différents genres de gravure, comment reconnaître les fausses estampes et les faux papiers*. Par A. Broquelet (Bibliothèque pratique de l'amateur) Pp. 95 (Paris J.-B. Baillière et fils, 1930) 6 francs.
- (2) *Décoration des verres, émaux, céramiques*. Par Prof. Suzanne Zaborowska (Bibliothèque pratique de l'amateur) Pp. 90 (Paris J.-B. Baillière et fils, 1930) 6 francs.
- (3) *A Treatise on the Air Brush with Progressive Lessons*. By Samuel W. Frazer and George F. Stine. Pp. x+203 (London Chapman and Hall, Ltd., 1930) 12s. 6d. net.

THE first two works form a portion of a library for amateur craftsmen, but being written by cognoscenti, they should prove welcome to others also. (1), in successive chapters, deals with a brief historical survey, modelling, moulding, pyrography, adhesives, methods of engraving, lithography, photography, protecting engravings, framing, watermarks, mounting and wood gilding. In the space allotted are provided a large amount of useful information and many appropriate diagrams and illustrations, two of the latter (on pyrography) being from sketches by the writer of (2), which deals with a most interesting branch of art. But this manual is less satisfying than (1), for there is too much vapouring and too little practical exposition. The chapters relate to decoration of glass of various kinds, enamels and ceramics. Stained and leaded glass are well treated. "Nous avons expliqué les différents procédés" (p. 65) is not self-evident. The writer is a mistress at her craft and has a vigorous stroke for illustrations; she shows vividly how to adapt natural to conventional treatment. Special mention may be made of the stork (Fig. 25) and the strawberry leaf (Fig. 49). The third book is a very masterly exposition of that modern tool, the air-brush. The literary style is unexceptionable, the information direct and well balanced, and the illustrations as effective as American work is apt to be. There is

no doubt that the use of the air-brush can be well learnt from this treatise. There are, however, many who would still prefer the older method of brush treatment

*Applied Mathematics for Engineers* By T Hodgson Vol 3 *Differential Equations with Applications* Pp viii + 320 (London Chapman and Hall, Ltd, 1931) 13s 6d net

FOLLOWING the very lucid and interesting application of the calculus to dynamics, given in vol 2, Mr Hodgson has produced an excellent sequel in the present volume. The course has been thoroughly well planned and clearly dealt with. The subject matter embraces ordinary equations, simultaneous linear equations, partial differentiation and equations, with two good chapters on double and triple integration and spherical trigonometry.

The theoretical aspect has been well developed, though not, perhaps, with the strict rigour so dear to the pure mathematician, for this would be quite out of place in such a book. Nevertheless, just as much theory as is essential to the intelligent understanding of fundamental processes is given, so that the engineering student need no longer be a mere seeker after ready-made formulæ, but may acquire an efficient mathematical equipment by which he can be certain that his calculations are based upon a sure foundation. The chapter on partial differentiation is a striking example of the skill by which the author develops the theoretical basis. An index is unfortunately omitted from the *y* in the sixth line from the bottom of p 80.

Not the least interesting part of the book is its manifold applications. These are carefully selected and demonstrated with great clarity. Beginning with the usual deflexion of beams, the author leads on to thermodynamic problems, harmonic analysis, and alternating currents, which are dealt with by vectors, by complex quantities, and by the Steinmetz operator. Numerous exercises for the student are also provided and these have evidently been carefully selected so that few problems of purely academic interest have been included.

(1) *The Macmillan Table Slide Rule* By Prof J P Ballantine Pp 4+4 slides+4 plates (New York The Macmillan Co, 1931) 2s 3d

(2) *Natural Trigonometric Functions to Seven Decimal Places for every Ten Seconds of Arc, together with Miscellaneous Tables* By Howard Chapin Ives Pp vi + 329 (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1931) 45s net

(1) FOUR plates contain five figure tables of  $10^\circ$ ,  $10^{10^\circ}$ , arc sin  $10^\circ$ , arc tan  $10^\circ$ . The four slides consist of tables of  $10^\circ$ ,  $10^{-2}$ ,  $10^{22}$ . By aligning the slides on the appropriate plate all the usual slide rule calculations which depend on log  $x$  and log log  $x$  can be performed. The alignment needs great care if a wrong reading is to be avoided.

(2) The main table gives on 270 pages natural sines, cosines, tangents and cotangents for every

10 seconds of arc, each page covering a range of 10 minutes of arc. The functions corresponding to an integral number of minutes are more boldly printed. The effect is pleasing and makes the table convenient in use. First differences and proportional parts are also given. The remainder of the book contains various subsidiary tables connecting chords, arcs, radii and central angles in a circle, adapted to the use of railway and road engineers. The book concludes with trigonometrical formulæ and an explanation. The origin of the values in the main table is not mentioned. The author states that the manuscript was twice checked and the proofs read four times and by three persons. The binding is strong and the printing is excellent

*Motor Benzole its Production and Use* By W H Hoffert and G Claxton Pp xxi + 689 (London The National Benzole Association, 1931) 25s

FARADAY discovered benzene, Perkin made synthetic dyes from aniline, it was found to be an easy step by nitration and reduction from benzene to aniline. Benzene became ennobled, the world preened itself in a coat of many colours, and birth was given to the great dyestuffs controversy which, perhaps, has now found an honourable senescence amongst the acts in the Expiring Laws Continuation Bill. Now a new child has been born, motor benzole, with a more aristocratic name. After one or two false starts in 1903 and 1907, it became an established fact as a fuel in 1913, and now National Benzole pumps are to be seen every few hundred yards on our highways. The proportion of the total production used—Prof H E Armstrong terms it misused—by the motorist increases each year, and considerably exceeds that required by the dye-maker, who, however, has to pay the higher price based on the fuel value of the spirit.

Benzole is extracted in gas works and coke ovens, but nothing like the total quantity possible is recovered. Some day a commercial synthesis of benzene will be achieved. It takes a book of more than 600 pages, including 120 tables, to tell us about motor benzole from every aspect of practice and theory. It is authoritative since it is prepared under the auspices of the National Benzole Association, which has established a highly competent research department.

*The Problems of Evolution* By Prof A W Lindsey Pp xiii + 236 (New York The Macmillan Co, 1931) 8s 6d net

THE object of this essay is to show how impossible it is to separate heritage and environment in the study of evolution. This involves the author in a discussion of the inheritance of acquired characters, and references are given to much recent research. The limitation in its application to the methods of evolution lies in the difficulty of associating the responses of somatic structures with the germ cells. The book will be useful to teachers and students of biology for their lighter reading. They must be critical, and they should try some experiments for themselves.

## Scientific Centenaries in 1932

THE value of the commemoration of the centenaries of notable men of science, of famous institutions, and of important discoveries, was demonstrated in many ways in 1931. The various celebrations not only gave opportunities for recalling great achievements but also provided occasions for reviewing the progress made in scientific research and its application to industry, and for stimulating public interest in modern developments. But apart from any direct gain which arises from such celebrations, it is only just that tribute should be paid to the memory of those who in the past have added to the spread of natural knowledge.

Foremost among the centenaries which fall within the year 1932 is that of Sir William Crookes, who was born on June 17, 1832. From the time of his discovery of thallium in 1861, until his death in 1919, he was in the front rank of investigators, while from the day he first published the *Chemical News* in 1859, he gradually attained to the highest eminence as a leader of scientific thought. His presidential address to the British Association in 1898 will long be remembered, while his name is to be found among the Copley medallists and the presidents of the Royal Society.

Born three months before Crookes, the eminent French man of science, Charles Friedel (1832-99) was both chemist and mineralogist. He assisted to found both the French Chemical Society and the French Association for the Advancement of Science and was the successor of Wurtz at the Sorbonne. Another chemist, born in 1832, who achieved distinction was Walter Weldon, who from journalism turned to scientific studies, and by his introduction of the manganese recovery process in the manufacture of chlorine, cheapened, as Dumas said, "every sheet of paper and every yard of calico throughout the world."

To the year 1832 also belong the names of Cailletet, König, Varley, Wimshurst, and Sir Charles Bright. Louis Paul Cailletet (1832-1913), one of the greatest ironmasters of France, in 1877, at the same time as Pictet, liquefied oxygen. He has been called the 'father of modern cryogenics'. Rudolph König (1832-1901), a German instrument maker of Paris, was well known for his researches in acoustics, James Wimshurst (1832-1903), the Board of Trade ship surveyor, built influence machines which did much to revolutionise the science of static electricity, Samuel Alfred Varley (1832-1921) was the inventor of the compound-wound dynamo, while Sir Charles Bright (1832-88) will always be remembered as a pioneer in submarine telegraphy. He was only twenty-four years of age when, in 1856, he joined with Brett and Cyrus Field in planning the project for the first Atlantic cable.

To these names may be added those of Nicolas August Otto (1832-91), originally a commercial traveller, who is remembered to-day for his outstanding work on the internal combustion engine, Gustave Eiffel (1832-1923), whose great tower was

but one of many notable civil engineering works for which he was responsible, Alexander Lyman Holley (1832-82), "foremost among those whose genius and energy established in America and improved throughout the world the manufacture of Bessemer steel", and Octave Chanute (1832-1910), another engineer, who became a pioneer of gliding and whose "Progress in Flying Machines" published in 1894 is a mine of information on early aeronautics. Chanute was born in Paris, but was taken at the age of six to America, where all his work was done.

The following were also born in 1832. Henry Seebohm, author of the "History of British Birds and their Eggs" (4 vols, 1882-85), Sir William Turner, formerly professor of anatomy in the University of Edinburgh and president of the British Association at the Bradford meeting in 1900, and Sir Edward Burnett Tylor, for whom a professorship in anthropology in the University of Oxford was instituted.

The losses in the ranks of men of science by death in 1832 were severe. Especially so was this the case in France, where an epidemic of cholera raged, which led to the death of eighteen thousand persons in Paris alone. Among the victims of the epidemic were Sadi Carnot (1796-1832), immortalised by his essay, "Reflections sur la puissance motrice de feu", Baron von Zach (1754-1832), the Hungarian astronomer who from 1791 directed the observatory at Seeberg, and General Berge (1779-1832), of the French artillery, one of the earliest students at the École Polytechnique, who drew the plates for Monge's "Géométrie descriptive". The Marquis de Jouffroy D'Abbans (1752-1832), the French representative among the pioneers of the steamboat, and Baron de Sané (1755-1832), the eminent naval constructor, "le Vauban de la Marine", who built the historic *Orient*, also died in 1832, as likewise did the veteran chemist Chaptal (1756-1832), and the great naturalist Cuvier (1769-1832). Both these distinguished men played a part in public affairs under Napoleon, and Cuvier, as permanent secretary of the Paris Academy of Sciences from 1803 onwards, was one of the most prominent among the brilliant group of French men of science of that time.

To these names must be added that of the young French mathematical genius, Evariste Galois (1811-1832), who was killed in a duel and whose tragic biography has been written by Dr G. Sarton, and also those of the Italian astronomers and ecclesiasts, Angelo Cesaris (1750-1832), and Barnaba Oriani (1752-1832), who made Milan Observatory famous, of Stephen Groombridge (1755-1832), the London merchant who compiled a star catalogue and helped in founding the Royal Astronomical Society, and that of Sir John Leslie (1766-1832), the successor of Playfair and the predecessor of J. D. Forbes in the chair of natural philosophy at Edinburgh.

Bicentenaries are naturally less numerous than centenaries, but many are of considerable interest

In 1732, for example, both Maskelyne and Lalande were born. For forty-six years Maskelyne (1732-1811) was Astronomer Royal, and to him was due the founding of the *Nautical Almanac*. Lalande (1732-1807) also has many claims to our homage. Indefatigable in his exertions on behalf of science, by his lectures at the Collège de France he gained for astronomy an unexampled popularity, and one of his books was called "the great newspaper of astronomy". It was to Maskelyne that Herschel first communicated the discovery of the heavenly body now known as the planet Uranus, but it was Lalande who wished to call it Herschel, a name it was actually known by for some years. Another astronomer born in 1732 was David Rittenhouse (1732-96), who succeeded Franklin as president of the Philosophical Society of Philadelphia and was among the first to welcome Priestley to America. The French mineralogist, Gabriel Jars (1732-69), the compiler of the "*Voyages métallurgiques*"; Alexander Cronstedt (1732-65), the Swedish discoverer of nickel, were also born the same year, as also was Richard Arkwright (1732-92), the greatest of the founders of our textile industry.

Carrying the survey a hundred years still further back, in 1632 Sir Christopher Wren and the great Dutch naturalist Leeuwenhoeck were both born, while that year saw the deaths of several mathematicians who were contemporaries of Kepler, Napier, and Galileo. The two British mathematicians, Thomas Allen (1542-1632) and Nathaniel Torporley (1564-1632), died in September and April respectively; the Dutch mathematician, Albert Girard (1595-1632), who collected and published the works of Stevinus and discovered various properties of spherical triangles, died in December; Lansberg (1561-1632), of Belgium, both mathematician and astronomer, whose tables were used by Horrocks, died in November; Christopher Borrus (1583-1632), of the Society of Jesus, who travelled to the Far East and in his charts of the Atlantic and Indian Ocean anticipated some of the work of Halley, died at Rome in May 1632, while another mathematician who died that year was Jobst Bürgi (1552-1632), whose system of anti-logarithms was worked out by him independently of the contemporary discoveries of Napier.

### Hydro-Electric Power Development in the Pyrenees.

By Dr. BRYSSON CUNNINGHAM.

AN interesting and efficient system of electric power generation and distribution, serving the Southern Railway of France (Chemins de Fer du Midi) and a number of important regional industries, has been developed, mainly during the past decade, from the natural water resources of the western Pyrenees. During a recent tour in southern France, I was afforded, through the courtesy of the Midi Company, an opportunity of visiting several of the generating stations, and the following is a brief description of the salient features of the undertaking, known as the Union des Producteurs d'Électricité des Pyrénées Occidentales (U.P.E.P.O.), which controls more than half a million horse-power, say one-fourth of the total water power developed in France, as registered at the end of 1930. The gross potential water resources of that country are estimated to be between nine and ten million horse-power.

The Pyrenees, forming, as is well known, the frontier barrier between France and Spain, with a length of about 240 miles between Cape Cerbera on the Mediterranean littoral and the south-eastern corner of the Bay of Biscay, apart from their engaging geological structure, present an interesting hydrographic feature, in that there is a marked difference in the rainfall and snowfall between the eastern and western halves of the chain, the quan-

tity being much greater in the west. I certainly acquired a confirmatory impression of the western abundance during three consecutive days spent in the neighbourhood of Pau in September, when the rainfall was almost incessant and its intensity surprising. The notable absence of glaciers in the

FIG. 1.—Cirque de Gavarnie.

eastern Pyrenees is accounted for by the insufficiency of the falls of snow for their formation. Obviously then, the great preponderance of moisture in the centre and west has marked out this region as a suitable area of exploitation for the development of hydro-electric power, and it is within the limits of the latitude of Oloron in the west and the

Val d'Aran in the east that the leading stations of the U.P.E.P.O. are located.

From the hydrographic point of view, several other characteristic features of the range lend themselves admirably to water-power development. Despite the general absence of great lakes, such as those in the Alps, there is a number of natural

stepped series, and two detached and isolated insulations. The chain lies in the upper valley of Ossau and commences at summit level with a source in the lake Artouste, a deep basin situated near the frontier line with its natural surface at a height of 1968.6 metres above sea-level. By means of a dam, the depth of water has been increased by 25 metres so as to form a reservoir with a capacity of 25 million cubic metres. From the lake a tunnel through the granite rock, 8.5 km. in length and about 6 ft. in diameter, conducts the water to a point just above the station of Artouste, which is entered by means of three pressure tubes under a gross head of 758 metres. The diameter of the tubes gradually decreases from 800 mm. to 600 mm. The flow actuates three Pelton wheels, each of 10,000 horse-power, coupled to three C.E.F. alternators of 7000 kw. capacity.

After passing through the Artouste Station, the water is received into two basins, each of 95,000 metres capacity, in succession, forming a working reservoir for the next station below at Miègebat, distant about 7.6 kilometres (Fig. 2). These basins also receive direct the waters of two mountain streams, or gaves: the Gave de Bious and the Gave de Brousset. The combined supply enters the Miège-

FIG. 2.—Miègebat generating station. The pipe lines are to the left and cannot be seen in the photograph. They enter the station across the bridge in the background.

basins of moderate extent which have been adapted as storage reservoirs for a working or a reserve supply of water, possessing potential energy of high value. In addition, waterfalls are numerous and lofty, being surpassed in Europe only by those of Scandinavia. The highest is the celebrated Cascade de Gavarnie with a fall of 1515 ft. The mountain streams or torrents which give rise to these falls are known locally as 'gaves'.

It is a curious feature of the topography of the Pyrenees that the upper ends of the valleys frequently expand into gigantic arcs of circles surrounded by towering, precipitous cliffs, crowned by snow and ice. These enlargements are designated 'cirques'. The most notable is the Cirque de Gavarnie at a height of 5000 ft. above sea-level, about a mile and a quarter in diameter, with rugged sides several thousand feet high, scored and intersected by hundreds of silvery cascades, including the Cascade de Gavarnie mentioned above (Fig. 1).

The U.P.E.P.O. came into existence in the early part of 1923, with the object of utilising to the best advantage the supplies of hydro-electric power in the western Pyrenees, by providing service lines to distant centres of consumption and by regulating the output of the various generating stations, using the surplus, after meeting the requirements of railway traction, for chemical and metallurgical industries. Eleven bodies are now affiliated to the Union, which possesses thirty 'centrales' or generating stations, totalling a maximum available power of 400,000 kva. and producing energy in a normal year to the extent of more than 1500 millions of kilowatt-hours.

Of the thirty stations, the Midi Railway Company operates five of the largest: three in a chain, or

FIG. 3.—Soulom generating station and pipe lines.

bat Station through four pressure tubes of 950 mm. diameter, under a net head of 380 metres. The generating plant consists of five Pelton turbines of 10,000 horse-power each and five alternators of 7000 kilowatts.

The next and final stage is the drop to the level of the station of Le Hourat, which is adjacent to

the head of the railway line at Laruns. The water is conducted through a canal having a length of 5.75 kilometres to four pressure tubes of 1200 mm. diameter, falling through which under a head of 204 metres, it actuates five Francis turbo-alternators of 10,000 horse-power each. Altogether, throughout the entire length of the Ossau Valley, there is plant for the development of 130,000 horse-power, producing 280 millions of kwh. annually.

The detached stations are those of Soulom and Eget. The former (Fig. 3) adjoins the railway line at Pierrefitte and is not far distant from the charming mountain resort of Caunterets, which is reached by an electrically operated tramway. The station at Soulom receives supplies of water from the Gave de Pau and the Gave de Caunterets under very different heads—the former being low and the latter high—necessitating two distinct forms of generation. The net fall of the Gave de Caunterets is 240 metres, and the water is conveyed through three pressure tubes of 810 mm. diameter to two Pelton wheels of 3500 horse-power, each coupled to alternators. The fall of the Gave de Pau is only 106 metres, and in this case the three pressure tubes have a diameter of 1200 mm. and the generating plant consists of three Francis turbines of 3500 horse-power each. The total capacity of the station, accordingly, is 21,000 horse-power, and its annual output is 80 million kwh. It is the smallest of the Midi installations, and was inaugurated before the War. A curious feature which I noticed is the variegated colouring of the pressure tubes, which, at first glance, I thought might possibly be a relic of War-time camouflage, especially as it had a faded appearance. I was told, however, that it was an attempt at æsthetic treatment with the view of harmonising the appearance of the pipes with the mountain background. As such, it could not be considered altogether successful. If a pipe line can be hidden or rendered less obtrusive by shrubs and vegetation, the advantage from a scenic point of view is, no doubt, considerable, but variegated tinting of the pipes only seems to produce a tawdry and unquestionably artificial effect.

The last station to be noticed is that of Eget (Fig. 4), which is located in the high valley of La Neste de Couplan. It benefits in part from an arrangement made in 1870 by the French Minister of Agriculture in order to create dry weather reserves to feed the lakes of the region, the streams of the plateau of Lannemezan, and the district of Gers. The following four lakes have accordingly been impounded so as to provide increased capacities, namely:

|             |                 |
|-------------|-----------------|
| Orédon      | 7,000,000 cu.m. |
| Cap de Long | 7,000,000 "     |
| Aumar       | 1,100,000 "     |
| Aubert      | 4,500,000 "     |

In addition, the Midi Company, by means of a barrage, has formed in the valley of the Oule an artificial reservoir of 6,500,000 cu.m. capacity, receiving supplies from a catchment area of 30 square kilometres. This brings the available reserves for the Eget Station up to 25 million cu.m.

The head at the station is 710 metres, and the water passes through seven tubes of 560 mm. diameter to a corresponding number of turbo-alternators of 5000 horse-power each. The mean annual output is 90 million kwh., of which 30 millions, due to stream flow, must be consumed between the months of April and July, while the remainder, provided by lake supply, can be consumed as required.

Time did not permit me to visit any stations outside the Midi groups. With three exceptions,

FIG. 4.—Eget generating station and pipe lines.

however, the rest are of relatively minor calibre, that is, less than an aggregate of 20,000 horse-power per station. The largest is one of 50,000 horse-power at Pinet, operated by the *Énergie Électrique du Rouergue*. Two others, of 35,000 and 33,000 horse-power respectively, belong to the *Société Hydroélectrique de la Cère* and the *Sté. des Forces Électriques de la Vallée de Gavarnie*.

An account of the stations can scarcely be considered complete without some reference to the system of distribution, which is very capably organised and constitutes one of the chief duties and responsibilities of the Union. The U.P.E.P.O. takes delivery of the energy furnished by its affiliated concerns at a tension of 60,000 volts at one or other of two transformer stations at Lannemezan or Laruns, belonging to the Midi Company, where, apart from a quota to meet local demands, it is transformed to a voltage of 150,000 and dispatched in the directions of Bordeaux and Toulouse. Each concern undertakes the transport of its own output to the points of delivery. Two lines of

50,000 kw. convey the current to Bordeaux and one of 50,000 kw. to Toulouse and beyond, the total distance exceeding 500 kilometres. At the two extremities of the high-tension system (Bordeaux and Toulouse) and at the intermediate point of Dax there are transformer stations to reduce the voltage again to 60,000. The various demands of traction and industry are met from these centres, as well as from those of Laruns and Lannemezan.

The duties of the central organisation of the U.P.E.P.O. at Tarbes are considerable. Each day it is furnished by its constituent units with detailed particulars of the previous day's output, the energy available, the local requirements, the state of the water supply, lake levels, etc. From these data is prepared a chart of the aggregate resources, and a scheme of apportionment is arranged to meet the fluctuating demand, the

deficiency at one centre being made good by the surplus at another. The whole system is planned, in fact, with the view of eliminating unnecessary waste, obviating local breakdowns or shortage, and ensuring a regular and sufficient supply for the needs of the important region which it serves.

My acknowledgments are due to the U.P.E.P.O., as well as to the Midi Railway Company, for information courteously placed at my disposal and for their kind assistance. The photographs of the stations have been supplied by the Midi Railway Company, from which I learn that, up to the date of writing, a length of 1256 kilometres (say 785 miles) of track is electrically operated, representing about thirty per cent of the whole system. A further 336 kilometres is now being equipped for electric traction, and the electrification of a length of 270 kilometres is under consideration.

### Obituary.

DR. J. P. LOTSY.

THE death of Dr. Johannes Paulus Lotsy, which occurred at Leyden in November at sixty-four years of age, terminates the career of one of the leading workers of the day on evolution and heredity.

Dr. Lotsy's botanical work began when he was sent out to the East Indies in 1896 to study the alkaloids contained in various species of *Cinchona*. The results of his work were published in 1898. He then settled down to a long career of teaching and research in Leyden, varied by frequent visits to almost every part of the globe. In 1906 he published the first part of his "Vorlesungen über Deszendenztheorien", the second part of which appeared two years later. This very useful work was based on his lectures on evolution at Leyden and comprised a comprehensive survey of the state of evolutionary thought at the time. At the same time another monumental work began to appear, "Vorträge über botanische Stammesgeschichte" (3 vols., 1907-1911), an unfinished treatise on the plant kingdom from a phylogenetic point of view.

Lotsy now began to develop the views on evolution and the species question with which his name will always be associated. During the years 1912 to 1916 he published a series of papers putting forward the view that the fundamental unit of taxonomy was the homozygous biotype, and that to this only should be given the name species. Subsequent work has shown that such a unit has no existence in ordinary allogamous populations, and later on Lotsy himself abandoned his opinion and went to the further extreme of doubting the existence of such homozygous biotypes in Nature even in pure lines.

In 1916 Lotsy published his well-known book, "Evolution by means of Hybridisation", in which he vigorously attacked de Vries's work on mutations in *Oenothera*, and claimed that the phenomena observed in that genus were due to the heterozygosity of the material. He advanced the view that the sole method of evolution was by means of hybridisa-

tion, and denied that gene mutations played any part. The book was written in a style entirely the author's own, and many of his views cannot now be maintained, but, nevertheless, it will remain a classic in evolutionary literature. Lately, moreover, evidence has accumulated showing that hybridisation plays a greater part in evolution than Lotsy's critics imagined. One of the most striking examples of this is the grass *Spartina Townsendii*, which has recently been shown, beyond doubt, to have originated from a cross between *S. alterniflora* and *S. stricta*, followed by a doubling of the chromosomes. Other cases could be quoted, and it seems clear that one of the means of evolution of new species is interspecific hybridisation followed by chromosome doubling.

During the last six years, having given up regular teaching on being made emeritus professor at Leyden, Lotsy visited New Zealand, South Africa, and other parts of the world for the purpose of collecting evidence for his views on evolution. He was a tireless worker in the field, and everywhere he went he amassed a wealth of material and brought together a great number of arguments in support of his views. In South Africa he worked especially on the genera *Cotyledon* and *Euphorbia*, and took back material of the former genus to Leyden, where he was breeding them on a large scale. He also turned his attention to hybrid populations in the human species, and a large part of the paper on his South African work, published in conjunction with Dr. Goddijn, deals with the various races he had studied there.

At the time of his death, Lotsy was engaged on a large work dealing with his ideas on evolution, and it is much to be regretted that he did not live to bring it to completion.

Lotsy was always a welcome visitor to Great Britain, his last visit being to attend the London meeting of the British Association. His views, always frank and forcibly expressed, were very stimulating and were generally appreciated; since,

however, he was apt at times to disregard the opinions of some of his botanical colleagues, his theories and conclusions have not perhaps received the recognition which they merit

#### PROF HUGO DE BOCKH

THE recent death at the age of fifty-seven years of Hugo de Bockh will occasion deep grief amongst those who in many lands enjoyed his gifts of friendship, admired his independent judgment and vigorous personality, and feel the loss to science. He was the son of a distinguished Hungarian geologist, and received part of his training under Karl von Zittel at Munich. In 1902, at the age of twenty-eight, he was appointed professor of mineralogy at the Hungarian School of Mines at Selmeczbánya, and there turned his attention to economic geology and to the tectonic problems which he realised would prove of practical value in mining. He wrote a text-book on geology in Hungarian, and amongst other investigations studied the applications of the Eotvos balance to subterranean prospecting. During the War he was appointed Under-Secretary for Mines in Hungary.

In 1923 de Bockh received the appointment which gave him his great opportunity—he became the geological adviser to the Anglo-Persian Oil Company, and had a great influence in its development by his superintendence of its geological work. He was in charge of its surveys in Persia and Mesopotamia, Albania, Colombia, and Venezuela, and of the international survey of the oil-fields of Iraq. In this work his indomitable, restless energy, originality and insight, and his inspiring enthusiasm made him a most efficient leader in the pioneer field work.

Prof de Bockh was asked to succeed Baron Nopcsa in 1929 as director of the Hungarian Geological Institute, and returned to Buda-Pest in 1930. He was given a seat in the upper house of the Hungarian Parliament. It was hoped that as soon as he had reorganised the Hungarian Geological Survey he would have time to publish the general conclusions of his world-wide study of oil-fields and their structures. He had published relatively little, partly owing to lack of time and to much of his work being confidential. His most important contribution was that, in conjunction with Dr G M Lees and Mr F D Richardson, to the British Association symposium on the structure of Asia (1929), in which he included some striking results of a study of the Magdalena rift-valley in Colombia.

Prof de Bockh gave early this year a series of lectures under the auspices of the University of London, in which he summarised his general conclusions on current tectonic problems, and showed his independence of judgment by emphasising the need for caution with Eotvos balance observations and deductions from isostasy. It is to be hoped that those lectures will have been left in a form available for publication, as they state the matured judgments of a geologist of unusual insight and of unique experience and qualifications.

#### MR J H LEONARD

By the death of John Henry Leonard, which took place at a Kensington nursing home on Dec 4, the Trustees of the British Museum have lost the services of one who was the first to hold the office of guide-lecturer at the Natural History Museum. The appointment was, at the beginning, regarded purely as an experiment, and was the result of the steady campaign conducted by the late Lord Sudeley to make the great national museums more attractive and more interesting to the general public.

That the experiment was such an undoubted success at the Natural History Museum was due to Mr Leonard's qualities, which rendered him so eminently fitted to discharge the duties of the post. To hold the attention of a group of people haphazardly brought together for a tour of part of the Museum, and with very varying capacity for understanding and appreciating what they were shown and were told, is no easy task, especially round exhibition cases in galleries of difficult acoustical properties. Mr Leonard possessed the fundamental quality of a good carrying voice, and at the same time was successful in appraising the mentality of the average listener, he was always patient of questioners and took great pains to enlighten the genuine inquirer. With school children he was particularly successful, partly because he was naturally fond of young people, and there are many, of tender years when they first visited the Museum, who will ever bear him in kindly remembrance.

Born on April 19, 1864, Mr Leonard was educated at Kensington Grammar School and at King's College and University College, London. He obtained the B.Sc. degree, his subjects being zoology, botany, and geology, in the last of which he gained honours. He taught science for a time, and was associated with the science sections at some of the exhibitions held at Earl's Court and Shepherd's Bush. He was appointed guide-lecturer at the Natural History Museum on May 20, 1912. Without having written anything, he has done no mean service in awakening an interest in natural history among those who, to the average annual number of 12,500, have attended his tours. He was also a lay reader for whose services in the pulpit there was always a good demand.

WE regret to announce the following deaths

Dr Melvil Dewey, formerly director of the New York State Library, originator of the decimal system of book classification, on Dec 26, aged eighty years.

Mr Beeby Thompson, formerly principal of the Northampton Technical School, who was a well-known consulting water engineer, on Dec 12, aged eighty-two years.

Prof Hermann Thoms, formerly director of the Pharmaceutical Institute of the University of Berlin and president of the German Pharmaceutical Society, aged seventy-two years.

## News and Views.

### Calendar of Geographical Exploration

THE century in which we live, young as it is, has yet been remarkable for its achievements in exploration. Both poles have been reached, much of the previously unconquered Sahara has been explored, surveys have been carried out in the north polar basin, in the antarctic regions, and in north-east Siberia, where a new range of mountains is known, but not yet marked on our maps. Attempts have been made to scale the heights of Everest. Expeditions such as those organised by Sven Hedin, Sir Aurel Stein, and R. Chapman Andrews in Central Asia, and by L. S. B. Leakey in East Africa, have contributed rich stores of geographical, geological, and archaeological knowledge of these regions. In spite of the accumulated experience of centuries and the increasing mastery over the elements which modern science is bringing to mankind, explorers still face situations which call for courage and sacrifice. Men like Oates and Amundsen have continued the tradition of heroism, and their names are added to the long list of pioneers who have willingly sacrificed their lives for others.

INEVITABLY, the character of exploration is changing from the extensive to the intensive. Regional survey in its widest sense, including a study of geology, past and present climates, flora and fauna, and human cultures, is rousing interest in the popular, as in the scientific, mind throughout the world. Scientific regional survey is specially developed in modern Russia and has proved of economic importance in the opening up of the apatite district of the Khibinsk tundra and in the discovery of naphtha-bearing beds in the Urals. The revival of interest in geography in the British Isles is evidenced by its recent inclusion as a separate subject of study in British universities. Our calendar for 1932 will record some outstanding events in the history of exploration. Appropriately enough, the first entries (p. 33) include the names of Scott, Shackleton, and Hassanem Bey, whose work, both from the point of view of science and from that of heroism and endurance, shows our century taking its place in the best traditions of exploration.

### Geological Exploration of the Andes

PROF. J. W. GREGORY is leaving England on Jan. 4 with an expedition to investigate some little-known parts of the coastal cordillera of southern Peru and their relations to the Andes and to the recent extension of South America into the Pacific. It is hoped to examine especially the structure of the part of the Peruvian coast that trends from north-west to south-east, and the geology of the desert belt between that coast and the western front of the Andes. A geological section is also to be prepared across the little-known belt between Ica and the Urubamba valley. The earth-movements and volcanic epochs of the Andes appear to have significant correspondence in date with the main stages in the formation of the Great Rift valley that were discovered in its exploration by Prof. Gregory thirty-

nine years ago. The expedition will descend from the Andean plateau down one of the head streams of the Amazon, and may return to England across Brazil. Miss McKinnon Wood will accompany the expedition especially to collect fossils. Mr. A. V. Coveley Price will join the expedition at Lima. The work will be helped during parts of the journey by Mr. M. A. Tarnawiecki and Señor Don Alberto Calderon.

### Old London Bridge.

THE Exhibition commemorating the centenary of the demolition of old London Bridge, which was opened on Nov. 5 in Regis House, close to the northern end of London Bridge, is to remain open until Jan. 24. The display has been organised by the Rev. H. J. Fynes-Clinton, rector of St. Magnus the Martyr, to raise funds for the restoration of Wren's tower and spire, and many societies and individuals have sent exhibits to it. The series of engravings, water-colours, and prints of the old bridge at various periods of its existence, with and without the houses upon it, and with the new bridge being erected close to it, are of very great interest to students of the history of London, while the two splendid models by Mr. J. B. Thorp are alone worth the trouble of a journey to the spot. The first of these is a 25-ft. model of the old bridge as it was about thirty years before the Great Fire. At the Southwark end are the water-wheels for corn grinding, while at the City end are the water-wheels erected in 1582 by the Dutchman, Peter Morice, for working the pumps which supplied water from the river to certain parts of the City. Mr. Thorp's other large model shows a London street with the Lord Mayor's show passing along it in 1616. Lectures are given on these models at short intervals. While these exhibits are perhaps of general interest, there are others which will appeal to the historian, the antiquary, and the engineer.

### Early Cloth Fulling.

AT a meeting of the Newcomen Society held in Prince Henry's Room, Fleet Street, on Dec. 16, Mr. E. Kilburn Scott read a paper on early cloth fulling and its machinery. Though it has remained for modern science to explain what happens to woollen threads when cloth is treated with moisture, heat, and pressure, the process of fulling, which involves the use of all three, goes back to very early days. There are references to fullers in both the Old and New Testaments, in the city of Pompeii can be seen pictures of the various processes of the fuller's craft and a fullery complete with its basins, cisterns, and compartments, and no one knows when machinery was first introduced which superseded the use of the hands or the feet in fulling. The object of fulling is to fill the interstices of the cloth as woven, to add to its appearance, its strength, and its 'feel', and the coarser the cloth the greater amount of fulling required. Cloth to-day is either treated in fulling stocks, in which are incorporated stamps which are worked somewhat in the same manner as tilt hammers,

or in milling machines with rollers. The fulling stocks have been known for several centuries, but the milling machine was first introduced by John Dyer, of Trowbridge, Wiltshire, who took out patents in 1833 and 1838. Mr Kilburn Scott himself was brought up in the works of Kilburn of Leeds and has been familiar with textile machinery all his life. His paper contained much of interest to the antiquarian, the inventor, and those connected with the cloth industry.

#### Progressive Science and Happiness

• AMONG the publications issued in the United States with the object of directing attention to the value of science and engineering in human progress, are the Research Narratives, published monthly as small folders by the Engineering Foundation, the joint research organisation of the four leading engineering societies of America. Hitherto, these narratives have covered a wide range of subjects, but the last three numbers contain the first contributions by various writers, dealing with benefits from engineering progress. Happiness, it is remarked, has ever been a condition that human beings have earnestly desired, but the question may be asked: How wisely has mankind used the means of happiness provided by engineering? One of the problems yet to be solved is the maintenance, without disastrous fluctuations, of the steady flow of enjoyment through well-ordered production, distribution, and consumption. "The present conditions", says one contributor, "are difficult to contemplate with mental serenity and undisturbed confidence, but they carry more of ultimate value than the prosperous years that preceded them." Many interesting views are expressed, and Dr C. E. K. Mees, director of research of the Eastman Kodak Company, after remarking that happiness is not a thing which depends upon the possession of material things beyond a certain minimum, concludes his article by saying: "I believe that a large portion of mankind will abandon the feverish quest for material things and will employ its greater leisure in the development of art and the cultivation of its soul." The wise use of leisure is certainly one of the problems which is becoming of increasing importance, but perhaps the greatest problem of the moment is the provision for every one of that minimum of material things, the want of which is felt by so many millions.

#### Commercial Crystalline Vitamin D.

THE investigations carried out during the past few years by Bourdillon and his colleagues at the National Institute for Medical Research on the formation of vitamin D have now led to the preparation of a pure crystalline compound, as recently reported by Askew, Bruce, Callow, Philpot, and Webster, in *NATURE* for Oct 31, p. 758. This compound, called by them 'Calciferol', is prepared by the irradiation of ergosterol in ethereal solution under strict anaerobic conditions, excess ergosterol being afterwards removed by fractional crystallisation and with the use of digitonin. The calciferol is separated from other products of irradiation by fractional crystallisation of the dinitro-

benzoates and subsequent hydrolysis of the ester. The process has now been repeated on a larger scale in the technical laboratories of Messrs The British Drug Houses, Ltd., London N 1. The sample of calciferol submitted is a white crystalline solid; it is stated to melt at 114.5° C., to have the same empirical formula as ergosterol, and to have the high vitamin D potency of 40,000 international antirachitic units per milligram. It is available for the use of research workers in tubes containing 100 mgm. The commercial production of pure vitamin D is a satisfactory culmination of the brilliantly directed but laborious research work of the Medical Research Council's investigators, and should lead to greater precision in therapeutics and to the possible discovery of new applications for its use.

#### 69-in Mirror for Perkins Observatory.

DR HARLAN T. STETSON, director of the Perkins Observatory, Ohio Wesleyan University, Delaware, Ohio, informs us that the large 69-inch mirror for the new telescope was installed at the Observatory on Dec 14. The disk of glass, weighing 3000 lb., was cast as an experiment in American glass making in the optical shops of the U.S. Bureau of Standards, in May 1927. The exceptional annealing of the glass, which required eight months of controlled temperature, facilitated greatly the polishing and figuring of the mirror's surface, which was executed in the factory of J. W. Fecker, in Pittsburgh. Exhaustive tests carried on at Pittsburgh by Dr Stetson, Dr J. S. Plaskett, of the Dominion Astrophysical Observatory, and I. C. Gardner, chief of the Division of Optical Instruments, of the U.S. Bureau of Standards, showed the surface to be of the highest order of excellence. Quantitative measurements revealed departures from the mean focus of twenty-five feet to be not greater than 0.01 in. for any zone. The completion of the Perkins telescope brings into the central States the third largest telescope in existence, the two other instruments of greater aperture being the 72-in reflector of Victoria, B.C., and the 100-in reflector at Mt. Wilson, California. These great telescopes in North America have all led the way to important additions to astronomical knowledge, and it may be confidently anticipated that the new instrument, under Dr Stetson's direction, will carry on the tradition.

#### Sixth International Congress of Genetics.

ACTIVE preparations are being made for the sixth International Congress of Genetics, to be held at Ithaca, New York, in August 1932. A series of quarterly bulletins of information has been issued and a number of committees has been at work for more than a year. A recent bulletin outlines the arrangements being made with regard to exhibits in connexion with the Congress. Several laboratory rooms will be used for cytological and other genetical exhibits, including recommended varieties of various crop plants. A new feature proposed is a genetical garden of three and a half acres, in which extensive exhibits of *Zea*, *Nicotiana*, *Oenothera*, *Antirrhinum*, *Petunia*, *Brassica*, and *Melandrium* will be grown from

seeds sent by geneticists in all parts of the world who are investigating these genera. Exhibits illustrating fruit breeding will be shown at the Agricultural Experiment Station, Geneva, New York, and an extensive series concerning human genetics is being arranged in connexion with the Third International Congress of Eugenics, to be held in New York immediately before, on Aug 21-23. A long series of animal exhibits, including domestic mammals and birds, fishes, insects, and molluscs, is also in preparation, the assembling of each group being in charge of a different person. Arrangements have been made for delegates to book passage on s.s. *Westernland* at a special rate of 200 dollars for the return voyage.

SUGGESTIONS have been made that the Congress should be postponed until world conditions improve, but Dr C C Little, of Bar Harbor, Maine, Secretary-General of the Congress, has issued a communication stating that the Council, after prolonged consultation, has decided not to postpone the Congress. Among the factors which influenced the Council in deciding to carry on the arrangements as originally intended, are the facts that a number of prominent European geneticists have already indicated their intention to attend, that a large number of lectureships for visitors to the Congress are being arranged by American universities, that obligations have already been made and commitments undertaken, and that early improvement in economic conditions is uncertain, making postponement inadvisable. Now that the matter is finally settled, it is hoped that all geneticists who can possibly do so will plan to attend.

#### Electric Equipment of the Dolomites Railway

THE narrow gauge Dolomites railway which joins Calalzo, in the Piave valley, to Dobbiaco, a distance of about forty miles, has now been working very satisfactorily for over two years. As the railway passes through Cortina d'Ampezzo, it is much frequented by tourists. The railway is operated by electricity and so there is no smoke and steam to detract from the beauty of the scenery. Fears were entertained in case, during heavy falls of snow, water would get into the motors and interfere with their working. A special arrangement was therefore devised for them so that when necessary they could be made 'enclosed' motors. Even in snow-clearing operations, when they were considerably overloaded, the motors suffered no damage. In the *Brown Boveri Review* for October, A Brodbeck gives an account of the electric equipment of this railway. It receives its power from a three-phase network at Calalzo at a pressure of 18,000 volts, but for operating the railway, direct current at 2700 volts is adopted. This is done by the use of only one substation situated near Cortina, a little more than half-way from the power terminus. The conversion of the alternating to direct current is done at the substation by means of two mercury arc rectifiers each of 11,000 kilowatts capacity at 3000 volts. It is interesting to learn that a momentary load of 200 per cent does them no harm, and that they can withstand a 25 per cent overload for half an hour. Owing to

the comparatively small currents they take, they require little space and their efficiency is extremely high, being 99.1 per cent over a large range of output. The use of rectifiers in railway plants is increasing, and we anticipate a rapid increase in the future.

#### Novel Slot Electricity Meter.

WE learn from *A E G Progress* for October that many hotel, boarding-house, and convalescent-home keepers now instal in their bedrooms a special slot meter to collect the cost of the electric energy consumed by the visitor. It is not uncommon for travellers to carry about with them all kinds of portable electrical appliances which are readily connected to the plugs in the bedroom, notwithstanding the printed regulations to the contrary. This sometimes leads to the blowing of fuses and is a source of fire risk to the building. It is therefore now not uncommon to put slot meters in the bedrooms, so that by the insertion of a coin the guest purchases a given amount of energy. Unlike an ordinary prepayment meter, the coin mechanism can be returned to the 'off' position by resetting a simple device. In this way the new visitor cannot consume at the expense of the previous one any energy that still may be available. The resetting device is actuated by a key, kept by the proprietor, who cancels for his own benefit the credit still due to the departing visitor. The company which makes this meter suggests that the constant source of revenue obtained in this way should be utilised to make the rooms more comfortable, and furnish them with plug points for all kinds of electric devices.

#### Indian Antiquities.

SIR EDWARD GAITT's review of British research work in India in the fields of archæology, philology, and ethnology in his address to the first meeting of the Royal Society of Arts in the current session (*Jour Roy Soc Arts*, Nov 13) records a remarkable achievement, especially when it is taken into account that such research, often demanding intense application, in the majority of cases has been no more than the distraction of a busy official career. India can now boast of an ancient civilisation and a literature, of which the older elements may go back so far as 2000 B.C., but when British rule began in the eighteenth century, Sanskrit literature and lore had lapsed into disrepute, the ancient monuments had been allowed to fall into decay, and the course of events in the Hindu period had been forgotten. From the time when the study of Indian antiquities was placed on an organised basis by Sir William Jones, who had gone to India as a judge of the Supreme Court in 1783, and the Asiatic Society of Bengal was founded, British officials have engaged in all branches of Indian studies with enthusiasm. Forgotten scripts, forgotten languages, and even forgotten empires have been rescued from oblivion, while the investigation of the customs, races, and religions of the people of India has been pursued in a scientific spirit without reference to racial or political prepossessions. Thanks largely to the efforts of

Lord Curzon, ancient monuments have been restored and the care of antiquities made a matter of administrative charge. It is to be regretted that Sir Edward Gait has to record a falling off in the number of British civil servants who now devote themselves to such studies, but on the other hand there is a measure of compensation in the fact that the number of natives of India who are interested in the history and antiquities of their own country is on the increase.

#### Birds of Paradise

In the Bird House and the small Tropical House adjoining it, the Zoological Society of London now exhibits a dozen species of birds of paradise, several of them recent arrivals along with the rare Matschie's tree kangaroo (see NATURE, Dec 12, p. 996), also coming from the Rawlinson Mountains in north-east New Guinea. Most noteworthy is the Emperor of Germany's Bird of Paradise (*Paradisea guineensis*), a species new to the collection, it bears a general resemblance to the well-known Lesser Emerald Bird of Paradise, but has the crown as well as the throat green, and the side-plumes shorter and of a different and less downy texture, more recalling the nuptial plumes of the egrets. Among those species that have been in the collection some time, special mention may be made of the Twelve-wired (*Seleucidus ignotus*), because of the peculiarity it exhibits of having the legs bare for some distance above the hock, as in a wading-bird. This peculiarity is shared by a very different bird from the same zoological region and also in the collection, the great black Palm-cockatoo (*Microglossus aterrimus*), this is noteworthy, for neither affinity nor habits can be invoked for the explanation of this nudity in these two species. A very humble bird by comparison, but also of much scientific interest, is a newly received specimen of the melanistic mutant of the blackcap, this variation, which is found in the Canaries and Azores, has been known for upwards of a century, and is called Heineken's Blackcap. The bird is on view in one of the small cages in the Bird House.

#### British Empire Hardwoods and Turnery

In Museum No. 1 in the Royal Botanic Gardens, Kew, a temporary exhibit of articles turned from Empire hardwoods by the skilled hands of Mr. A. L. Hetherington, assistant secretary in the Department of Scientific and Industrial Research, has been arranged. While indulging his hobby of turnery, Mr. Hetherington also carried on important research, for he worked upon some eighty different kinds of Empire woods, many of which are new to the turner, the results of his work being demonstrated by excellently carved boxes, chalices, tazzas, goblets, dishes, ash trays, and other articles. Particularly beautiful are a chalice made from sapodilla wood (*Achnas Sapota*), two tazzas made of African blackwood (*Dalbergia melanocylon*), a goblet of bulletwood (*Mimusops littoralis*), a string box of puriri (*Vitex littoralis*), and two match stands of gidgee (*Acacia Cambagei*). Mr. Hetherington has added to the value of his demonstrative work by writing an account of the various

kinds of wood used, with particulars of their peculiar working properties. This book has recently been published by the Empire Marketing Board under the title "British Empire Hardwoods from the Point of View of Turnery." After discussing the properties of eighty kinds of wood, he goes into further particulars about those he considers of greatest importance for ornamental turning. All who are interested in wood turnery should make an effort to visit Kew within the next few weeks and inspect this interesting collection.

#### Forest Survey by Aeroplane.

In the development and protection of Canadian forests, aircraft have come to play a most important part. The *Canadian Surveyor* for October in a general account of aviation in Canada explains how aerial photography is used to show the character, distribution, and accessibility of the timber; thus facilitating exploitation on sound lines. Even more valuable is the use of air patrols for noting forest fires, and of air transport in carrying crews and equipment for extinguishing the fires. In Ontario alone during the year 1929 more than three hundred fires were thus detected. Aircraft are also used in combating insect and other pests. These attempts are still in an experimental stage, but the results so far are promising. Areas of fir and spruce affected by spruce budworm and of hemlock and balsam affected by hemlock looper have been dusted with calcium arsenate from the air. The method is certainly cheap and fairly thorough. Experiments in Manitoba have shown the effectiveness of dusting wheat with sulphur in order to fight the destructive wheat stem rust. Aircraft are also being used to expose spore traps, in an endeavour to determine the spread of wheat rust and white pine blister rust.

#### Quantity of Matter in the Universe

In the discussions taking place at the present time on the structure of the universe, the amount of matter distributed throughout the whole of space is determined by calculating the total mass of existing protons and electrons. In all the celestial bodies revealed by the means of observation yet available, the whole number of these corpuscles is found to be  $10^{79}$ . All other hypotheses must, therefore, be based on this figure and on the dimensions of the radius of the universe. In a note by Prof. Gianfranceschi, broadcast from the Vatican on Nov. 26, it was pointed out that limitation of the consideration of this question to that of the matter constituting the corpuscles is scarcely justifiable. Protons and electrons represent a special, but not the original, form of matter. They exert forces of attraction and repulsion originating in their character as electrified corpuscles and in their masses, that is, in measurable magnitudes. The possibility of the transformation and formation of the corpuscles must, however, be assumed. In considering such changes, not merely the energy variations but also the inertia must be taken into account, and any theory of the universe which may be formulated, whether static or dynamic, should be based on these

active and passive principles jointly. The curvature of space is not produced solely either by the visible masses, which must be regarded as singular points of space, or by the energy transported in the form of photons, which in their turn can constitute only lines of singularity, but it must exist in a kind of background or support, filling the universe and composing real physical space. Thus it becomes necessary to be able to express the contribution of this real space, with its twofold element of energy and primordial inertia, to the geometrical scheme of the universe.

#### Flutter of Aeroplane Wings.

In 1928 a monograph on the "Flutter of Aeroplane Wings", by Messrs R. A. Frazer and W. J. Duncan, was produced at the National Physical Laboratory, summarising in a single useful volume the work that had been done by them on that subject up to that time. Since that period this work has been continued, while the associated problem of tail flutter in aeroplanes has also been the subject of study. A new volume has now been produced under the comprehensive title of "The Flutter of Monoplanes, Biplanes, and Tail Units" (Air Ministry Aeronautical Research Committee Reports and Memoranda, No. 1255 (Ae 404) The Flutter of Monoplanes, Biplanes, and Tail Units (a sequel to R and M 1155). By R. A. Frazer and Dr W. J. Duncan. Pp viii + 179 + 12 plates (London: H.M. Stationery Office, 1931, 7s. 6d. net), embodying results that have already been issued from time to time on wing and tail flutter under one cover. The subject is well illustrated by cinematograph pictures of some simple experiments designed to show the various types of flutter that may arise in practice, and the nature of the dynamical problems they expose. While much of the work is of a mathematical complexion, recommendations are included regarding the design of tail units and of biplane wings that should be exceedingly useful to designers. Altogether the monograph is a comprehensive record of a valuable series of investigations. It is understood that the subject of airscrew flutter, which has been under study for some time, will be produced in due course as a separate report.

#### Lead Content of Rocks

PROF. ARTHUR HOLMES points out that there is a serious discrepancy between the data for lead in rocks (a) as given by Prof. Hevesy and Dr. Hobbie and (b) as cited by him in the letters on this subject which appeared in *NATURE* of Dec. 19, 1931. The latter figures (under Pb on p. 1040) refer to the preliminary results obtained by the gravimetric method, whereas those announced on p. 1039 are the final results obtained by the use of the radioactive indicator method. Both sets of figures will appear in a forthcoming detailed record of the investigation. It appears that Prof. Hevesy substituted the final results for the preliminary figures after Prof. Holmes had passed the proofs of his own letter. The effect of the corrections, however, is to emphasise the validity of the conclusions based on the original figures. It now appears that in the composite sample of granitic rocks the

total lead is eight (not five) times the radioactively generated lead. Thus, if the atomic weight of the lead originally present in the earth be taken as 207.22, that of the lead now present in granitic rocks should be about 207.19. Actual determinations on ore-lead correspond very closely with these figures.

#### Prof. Alexis Saposhnikoff

News has been received that Prof. Alexis Saposhnikoff, the well-known Russian chemist, who, as recorded in *NATURE* of April 25, 1931, was arrested about a year ago and condemned to ten years' deportation, has had his sentence so far ameliorated that he is transferred daily to the 'Technical Bureau' under guard, where he works without pay, returning to prison in Leningrad at night. An escaped prisoner reports that he was confined with the "old Prof. Saposhnikoff. Frequently he gave us lectures on poison gas. He spoke well but I did not understand much. Prof. Saposhnikoff had been in prison for a year. The Interrogatories of the OGPU took place between eleven and three o'clock. Prof. Saposhnikoff was often disturbed and returned always very anxious. He and others had their food in the common canteen. Nothing was brought to them from outside, and visits were prohibited. It was like being in a tomb."

#### Announcements.

THE Astronomical Society of the Pacific has awarded its Catherine Wolfe Bruce Gold Medal for the year 1932, "for distinguished services to Astronomy", to Dr. J. S. Plaskett, director of the Dominion Astrophysical Observatory, Victoria, B.C.

It is announced by the Johannesburg correspondent of the *Times* that fire broke out in the main building of the University of the Witwatersrand on Dec. 24, destroying the Gubbins Library and Mrs. Hoernlé's ethnological collections, the Leonard Memorial Law Library, and a natural history collection. The damage to the building is estimated at £20,000.

It is announced by Science Service that Mr. Frederick Hodge has been appointed director of the South-west Museum, Los Angeles, California. Mr. Hodge is well known for his work on ethnology, having conducted several expeditions in order to study American Indian tribes. He was formerly editor of the *American Anthropologist* and of the "Handbook of American Indians", and in 1916 he was president of the American Anthropological Association.

At the meeting of the London Mathematical Society on Jan. 14, there will be a discussion on "Generalisations of Fourier's Integral". The discussion will be opened by Dr. Norbert Wiener, of Massachusetts, and Prof. G. H. Hardy, Prof. E. C. Titchmarsh, and Prof. G. N. Watson, among others, will take part in it. At the meeting on Feb. 4, Mr. M. H. A. Newman will deliver a lecture on "Topological Methods in the Theory of Continuous Groups". Members of other scientific societies who may be interested are invited to attend these meetings, which take place at 5 o'clock at Burlington House.

### Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

### Examination of Protein Films.

THE simplest types of molecular architecture are to be found in materials in the form of films. The examination of films of protein materials is attended with many difficulties, absent in the case of simpler organic substances like the fatty acids.

Whilst the long chain organic compounds containing polar groups can readily be converted into the state of uniform unimolecular films on liquid surfaces on account of their solubility in volatile non-polar solvents, this method is not available for proteins. The method of dispersing the protein in alkaline or acid solutions and spreading the dispersion on a water surface was adopted by Gorter and Grendel, who with the aid of a Langmuir trough obtained a series of interesting measurements on the force-area curves of various proteins. Optical ultra-microscopic examination of such films by Zocher and Stiebel revealed that, except in a few cases, for example, haemoglobin and casein on strongly acid solutions, protein films spread in this manner were not uniform, whilst the magnitude of the mean limiting thickness obtained, 9-10 Å, indicates either that films obtained in this manner even when uniform must be in a relatively close packed state or that part of the protein must have disappeared into the bulk phase. Denatured protein films alone appear to be formed from disperse solutions by the operation of the forces of surface tension, a somewhat lengthy procedure.

We have found it possible to spread a number of proteins such as egg albumen, gliadin, and glutenin in the form of highly disperse uniform films on the surface of water in the following manner: a thin quartz fibre which may for convenience serve as the arm of a microbalance is coated with pure paraffin wax of relatively low melting point. The surface of the wax is lightly dusted with the powdered protein. The protein is then rendered slightly moist by holding the fibre over steam until the increase in weight is some ten per cent of the weight of protein present. On touching a water surface with the fibre tip the protein spreads relatively slowly and apparently quite uniformly over the surface. The microbalance is readily calibrated by spreading myristic acid from the fibre, for both the force-area curves as well as the potential-area curves are well established for this material.

Some proteins, for example, keratin and the xerogel of gelatine, cannot be spread in this manner, and, indeed, unimolecular films of this latter protein do not appear attainable on water surfaces owing to the readiness with which the gelatine undergoes dispersion in the bulk phase. We have examined a number of such films with the aid of a Langmuir trough and, as was to be anticipated, their properties are distinct from the thicker films examined by Gorter and Grendel. In the case of gliadin, for example, a homogeneous film exerting a perceptible surface pressure is obtained with a surface concentration of  $0.36 \times 10^{-7}$  gm/cm<sup>2</sup>. On compression a linear force-area curve is obtained up to a surface concentration of about  $0.7 \times 10^{-7}$  gm/cm<sup>2</sup>. The form of the curve is altered by alteration of the acidity of the substrate. At higher compressions the film, originally fluid, under-

goes transition to a gel-like film. Over a limited range of pressure at least, this transformation appears to be reversible. The 'gel' form is curiously elastic, and the protein in this form may be related to that which, in the bulk phase, is generally described as denatured.

Examination of aqueous protein systems by the method of surface potentials gives us information even more complete than that obtainable from data on the force-area characteristics. It is found, for example, that no change takes place in the magnitude of the vertical component of the electric moments of the polar groups comprising the film material until the two-dimensional sol-gel transition sets in, an indication that this latter form is associated with some type of interaction of the polar groups in adjacent polypeptide chains. A study of the three-dimensional gels of gelatine by this method reveals the fact that the surface phase has a different setting point from that of the bulk phase and is essentially lyophobic in character, but the spreading of fatty acids over sols can readily be followed. The change in the air-liquid potential occurring on the tryptic digestion of an albumen film on a water surface by means of trypsin in the substrate is relatively large, about 75 mv, and permits of closer analysis of such chemical reactions occurring at interfaces.

The dependence of the rate of tryptic digestion in a bulk phase on the acidity of the environment is likewise to be observed in the surface reaction, but with phosphate buffer solutions there appears to be a shift towards the acid side of about 1 pH in the optimum acidity. The characteristic curve of the reaction of trypsin and egg albumen shows that the digestion of the albumen apparently takes place in stages and that an inhibition of the reaction can occur by means of an addition of small quantities of already digested albumen solutions. The digestion of egg albumen by pepsin reveals a simpler mechanism and no final solution of the egg albumen film takes place.

Preliminary investigation holds out some promise of obtaining more precise information both as to the constitution and reactions—general and specific—of protein films by these methods.

### Absolute Values of X-Ray Wave-lengths and the Fundamental Atomic Constants.

THE wave-lengths of the X-ray spectra are now known with a considerable degree of accuracy (in favourable cases to at least 1 in 100,000). But this means only that the ratio between the wave-lengths and a certain distance within a crystal lattice (for example, the distance between the atomic layers parallel to the cleavage faces of calcite) is measurable with this accuracy. The computation of the dimensions of the crystal lattice from the data involved (electronic charge, density of the crystal, and so on) give the absolute value of the atomic distance with only moderate accuracy (say 3 in 1000). It has therefore been necessary to fix an arbitrary value for the atomic distance in question and thereby for the scale of the X-ray wave-lengths, the *X units*. The agreement between this scale and the C.G.S. units is for this reason ascertained only within the last-mentioned limit. On the other hand, if we were able to fix the scale of the *X units* in centimetres, this gives us a possibility of determining in absolute values the atomic distances and, indirectly, the other fundamental constants (for example, the electronic charge).

A very direct method of determining the X unit in absolute value (centimetres) is to register on the same plate, and with the same spectroscopic outfit, some X-ray spectral lines which have been measured with crystal gratings, and some lines of ordinary spectra the wave-lengths of which are known in angstrom units ( $10^{-8}$  cm)

For this purpose only spectral lines of very short wave-lengths of the same order of magnitude as the X-ray lines (less than 100 Å) can be used. From researches carried out in this laboratory on the spark spectra in the extreme ultra-violet of highly ionised atoms, a number of such lines are now available and may be used for the purpose. Independently of these lines, which have been measured in higher orders by comparison with well-known lines, there is also a second method available, namely, to use lines of short wave-length the value of which can be calculated theoretically for simply built atoms.

The hydrogen-like atoms of the lowest elements may be used with confidence for this purpose. Through the researches in this laboratory, the Lyman series, formerly known for H and He, has been found for the next elements<sup>1</sup> Li III, Be IV, and B V. The wave-lengths of the first member ( $1^2S-2^2P$ ) are respectively Li III 135 01, Be IV 75 94, B V 48 585 Å.

The accompanying spectrogram (Fig. 1) shows,

FIG. 1.—Above, spark spectrum of carbon, below, X-ray spectrum of copper and carbon

|                                                  |      |                    | 10                                                         | C $K\alpha$ II   | $2 \times 44\ 50$ |

below, a number of X-ray lines the wave-lengths of which are known on the X unit scale. Above is registered a spark-spectrum of carbon with wave-lengths covering the same region. These lines belong to carbon atoms with one and two electrons (C VI and C V). Their values are now known in angstrom units. The first line of the Lyman series of carbon (C VI), which is seen as a strong line on the spectrogram, may be calculated from the hydrogen atom model with more than sufficient accuracy (as  $33\ 740 \times 10^{-8}$  cm). With the aid of all these lines in different orders it will be possible to establish the relation between the X unit and the angstrom unit (or the centimetre).

The spectrogram shown was taken with the spectrometer described by Siegbahn and Magnusson,<sup>2</sup> using a small plane-grating with 600 lines, the ruled surface

being 1 mm in width. Before giving definite values we wish to make exposures under varied conditions and using different gratings.

#### Experimental Proof of the Spin of the Photon.

In a paper under this title which has recently appeared,<sup>1</sup> we have described and discussed observations which have led us to the conclusion that the light quantum possesses an intrinsic spin equal to one Bohr unit of angular momentum. In the four weeks which have elapsed since that paper was put into print, the experimental technique has been much improved in the direction of attaining greater precision. It appears desirable forthwith to report our newer results, which confirm the conclusion stated above.

As mentioned in earlier communications,<sup>2</sup> the experiment we set before ourselves was to determine the extent to which the depolarisation of Rayleigh scattering of monochromatic light is diminished when it is spectroscopically separated from the scattering of altered frequency arising from the molecular rotation in a fluid. An important improvement on our previous arrangements is the use of a pointlike mercury arc, which enables an intense beam of monochromatic light to be obtained which is rigorously transverse to the direction of observation. In the case of the feeble scattering by gases, a serious source of error is the parasitic illumination from the walls of the containing vessel. We have succeeded in eliminating this by using the gas under pressure in a steel cross with suitable arrangements for securing a dark background. The depolarisation of the scattered light is determined photographically with a spectrograph and a large nicol placed in front of the slit. The use of Schwarzschild's formula for photographic blackening enables the ratio of the horizontal and vertical components of scattered light to be calculated from the times of exposure in the two positions of the nicol which give equal densities in the spectra.

Using alternately a fine slit and a very broad slit on the spectrograph, the depolarisations of the Rayleigh scattering and of the total scattering respectively are determined. The following table gives the values for the case of oxygen, carbon dioxide, and nitrous oxide gases under pressure.

TABLE. DEPOLARISATION PER CENT

| Gas              | Observed         |                     | Calculated                |             |
|------------------|------------------|---------------------|---------------------------|-------------|
|                  | Total Scattering | Rayleigh Scattering | Kramers-Heisenberg Theory | Spin Theory |
| O <sub>2</sub>   | 6.5              | 4.1                 | 1.7                       | 4.2         |
| CO <sub>2</sub>  | 10.3             | 6.3                 | 2.8                       | 6.7         |
| N <sub>2</sub> O | 12.0             | 7.7                 | 3.4                       | 7.9         |

The depolarisations of the total scattering given in column 1 thus found spectroscopically are in good agreement with the best accepted values determined by other methods. Column 2 gives the observed depolarisations of the Rayleigh scattering, column 3 the values calculated from the Kramers-Heisenberg dispersion theory, and column 4 the values calculated from the theory of the spinning

photons discussed in our paper. It will be seen that the values given by the latter are strikingly supported by the experimental results.

### Wave-length of the Green Auroral Line Determined by the Interferometer

SOME years ago Babcock<sup>1</sup> gave results of accurate measurements with an interferometer method of the green line which appears in the light from the night sky. We have reason to believe that this line is identical with the strong green line appearing in the auroral spectrum, but on account of the great interest attached to this line it will be of importance to measure accurately the wave-length of the green line from the aurora itself in order to settle the question as to the identity of the two lines.

As I mentioned in a report at the Congress of the Geophysical Union at Stockholm, I was preparing for such investigations to be carried out at the Northlight Observatory at Tromsø, recently built by grants from the International Education Board founded by Rockefeller.

The apparatus used consists of a Fabry-Perot etalon placed in front of the lens of a camera. Two silver-coated quartz etalons—about 2.5 and 5 mm thick—

FIG 1

were made by Messrs Adam Hilger, Ltd, London. Their optical thickness was measured by the National Physical Laboratory. The camera lens was an Eremen anastigmat of focal distance 10.5 cm and of high light power  $F$ , 1.18. The part of the light having a wave-length shorter than about 5200 Å was removed by a Wratten filter placed in front of the etalon. The whole apparatus was put into an isolated box, where the temperature could be measured and kept fairly constant.

Recently two exposures of interference fringes of the auroral line were made with the 2.5 mm etalon at the Tromsø Observatory, one on Sept 14 and the second on Oct 29. Both exposures showed a large number of fringes (on the original plate 18-20 could be counted), and no sign of doubling or dissymmetry of the line was to be seen. The neon line 5852.488 Å was used for comparison.

During the first exposures the regulation and measurements of the temperature were not satisfactory. During the exposures of Oct 29, however, the temperature in the box on both sides of the etalon was measured at regular intervals.

Diagrams of the interference fringes corresponding to the exposures of Oct 29 and obtained with a Moll microphotometer are shown in Fig 1. The curves (a) and (b) correspond to the auroral line and the neon line respectively.

Details regarding standardisation of the plates and

methods of calculation will be given in a subsequent paper. I will state here merely the results from the observations of Oct 29, which may be considered as satisfactory.

The wave-length was calculated in the following two ways:

(1) The vacuum wave-length is found from the equation

$$\lambda_N = \frac{2e\mu}{P_N} \quad (1)$$

where  $\mu$  is the refractive index and  $e$  the thickness of the etalon reduced to the temperature of observation,  $P_N$  is the order number for the centre of the auroral line ring-system. The true temperature was found by means of the neon line fringes.

(2) The comparison line was used directly and the wave-length found by means of the equation

$$\lambda_N = \frac{P_c \mu_c}{P_N \mu_c} \lambda_c (1 + \epsilon) \quad (2)$$

where  $P_c$ ,  $\mu_c$ ,  $\lambda_c$  are order number, refractive index, and wave-length corresponding to the comparison line,  $\epsilon$  is a small correction due to difference of temperature of the etalon at the exposure of the auroral line and that of the neon line. This temperature difference was measured directly.

Calculation according to (1) gave for the wave-length of the auroral line

$$\lambda = 5577.340 \text{ Å (I U)}$$

The second method gave

$$\lambda = 5577.345 \text{ Å (I U)}$$

The main error in our experiments is due to uncertainty in the temperature measurements, but should not exceed 0.01 Å. We are improving our arrangements so as to obtain a higher constancy of temperature.

As an average of his measurements, Babcock found  $\lambda = 5577.350$ . Thus, within the limit of error, the green line of the aurora is identical with that of the night sky luminescence.

### Some Effects of Turbulent Pressure

IN a recent paper Ertel<sup>1</sup> has shown, at some length, that turbulent motion in the atmosphere reduces the pressure, recorded by a barometer, by  $\rho w'^2$  dynes/cm<sup>2</sup>, where  $\rho$  is the density of the air and  $w'$  is the vertical component of the turbulent velocity. This result we can get quite simply from analogy with the kinetic theory of gases, as pointed out by McCrea<sup>2</sup>. Ertel estimates that a mean wind-speed near the ground of 10 m/sec would lower the local pressure by 0.08 mb, a calculation from the observations of Scrase<sup>3</sup> gives results of the same order.

It seems unnecessary that there should be equipartition of eddy energy in the three directions,  $Ox$  down-wind,  $Oy$  across, and  $Oz$  vertical, this, in fact, is shown from the observations of Scrase on pages 6 and 12 of the paper quoted. Considering in a general way the manner of formation of the eddies by friction at the earth's surface, one would suppose that the  $u'$  and  $w'$  components of the eddy motion would be of larger order than the  $v'$  (cross-wind) component, especially in observations taken over a short period, like one minute, but Scrase shows that the  $v'$  component is 30-50 per cent greater than the  $w'$ , particularly near the ground (1.5 metres).

Now consider two points  $P$  and  $Q$  at the same level and at, for example, 100 metres from one another across wind, then the surface 'roughness' at  $P$  and

$Q$  may well be different or the immediate past history of the air or  $P$  and  $Q$  may differ in height from the ground by perhaps 5-10 metres in undulating country. Any of these effects will cause a difference between the values of  $w^2$  at  $P$  and  $Q$ . But a difference of 0.001 mb in pressure over a distance of 100 metres in latitude  $55^\circ$  requires an air-flow of about 8 m/sec for stability. So the only way to avoid, maybe violent, readjustments is for the horizontal components of the turbulent energy to differ between  $P$  and  $Q$  by the same amount as the vertical components. This gives us at once that, for a steady state, the horizontal contributions to the eddy-energy at any point must differ from the vertical by an amount which is constant over a wide horizontal area.

When the mean wind velocity or vertical temperature gradients are varying every few minutes it will take time for the turbulent energy over some distance to readjust itself, this may account for the components of turbulent velocity measured by the standard autographic instruments being about three times as great, for the same mean wind-velocity, as those obtained from a light sensitive vane (Serase, loc. cit.) On a larger scale this readjustment is very likely a cause of the 'wind-swinging' described in a letter by Johnson<sup>4</sup> some years ago, he says that it is accompanied by microbarograph oscillations of the order of 0.05 mb, with a period of 6-8 minutes.

This also has some bearing on the turbulent motion of liquid between two coaxial vertical rotating cylinders. Taylor<sup>5</sup> has studied this problem. The work of earlier experimenters showed him that the turbulence could not be two-dimensional, he calculated the disturbance, if restricted to symmetry about the axis of rotation, and verified his calculations by experiment. But why should there never be two-dimensional turbulence? Ertel's result may show us. With the usual cylindrical co-ordinates,  $r, \theta, z$ , two-dimensional disturbances would be in  $r$  and  $\theta$  only, this would reduce the mean static pressure at the level,  $z_0$ , considered, but as the average depth of the liquid is not changed, vertical, or  $z$ -, disturbances must occur at the same time as the  $r$ - and  $\theta$ -disturbances in order to support the liquid above  $z_0$ . Two-dimensional turbulence is thus not possible in the motion of liquid between a pair of vertical coaxial rotating cylinders.

#### *Deinotherium* in the Pleistocene.

THE discovery made by the East African Archaeological Expedition on Nov 17 last, announced in the *Times* of Dec 3 (see also *NATURE*, Dec 12, p 995, and Dec. 26, p 1075), of *Deinotherium* remains in implementiferous Pleistocene deposits is extremely important. It is, however, not quite the first of its kind, for M Delpierre, a Belgian geologist who had been working on the sediments of the Albertine rift near Ngeti, told me, a year or two ago, that he had discovered *Deinotherium* teeth and bones in beds which, on other evidence, he was convinced are of Pleistocene date. He affirmed, too, that these most unexpected fossils were not derived

Now, at Kurungu in South Kavirondo, Kenya Colony, on Lake Victoria, there is a series of fossiliferous sediments, made known to geologists by the researches of Dr Felix Oswald, which largely, though not entirely, because they yield *Deinotherium*, are

regarded as Miocene, in spite of the fact that the contained Mollusca are all living species. In January 1930, I discovered large developments of these beds farther north, on Rusinga Island and on the mainland near it. The strata are there interbedded with lavas and volcanic tuffs which might well prove valuable for dating purposes over a limited area. Lying on these sediments I found a crude *coup de poing* which, judging from the appearance of its surface, seemed to have been derived from the underlying beds; but as these were to be dated as Miocene, I considered any such derivation impossible, and so regarded the artefact as a purely surface find and of little consequence. The Oldoway discovery, however, would seem to render the alternative explanation possible.

A study of the map is sufficient to show, apart from indisputable geological evidence, that Lake Victoria, with its drowned coastline and reversed feeders, is younger than the main river channels, the upper courses of which are submerged beneath it. Yet on the Kavirondo evidence, part of it at least dates back to the Miocene. Clearly, then, a difficulty would be solved if the deposits at Kurungu and Rusinga could be regarded as, say, Plio-Pleistocene, or lower to middle Pleistocene, and laid down, in part at any rate, during the first pluvial period—I long ago pointed out that if anybody wanted a pluvial period in the Miocene, the Kurungu could provide the necessary evidence—and from what has been said above, this interpretation is seen to be no longer out of the question. But there is more. Controversy has arisen between Prof J W Gregory and the East African Archaeological Expedition (1926-27 and 1928-29) concerning the age of the Kamasian beds in the Eastern Rift valley. Gregory correlates these with the Karungu deposits, and therefore regards them as Miocene, but Leakey, on the sound evidence of the discovery of stone tools therein, regards them as Pleistocene and laid down during the first (Kamasian) pluvial period. It would appear then, in the light of the discovery of *Deinotherium* in Pleistocene beds at Oldoway, and the possibility that my *coup de poing* was derived from beds of Karungu date, that Gregory's correlation is not unsound, as Leakey thought, and that the artefacts were in the Kamasian beds, which Gregory disputed. (In this connexion see *NATURE*, Dec 19, p 1019.) Moreover, if this contention is admitted, another riddle in the history of Lake Victoria is satisfactorily solved.

#### Ether-Drift and Gravity

It is well known that, by means of electrodynamic experiments, no one has yet succeeded in ascertaining the cosmic movement of the earth, which, particularly in relation to the spiral nebulae, amounts to very high velocities. Apart from the still incompletely explained results obtained by Miller, which, from the work of Joos, should undoubtedly be considered as perturbations, Courvoisier at Potsdam and Esclançon at Strasbourg recently got positive results. These are interpreted by Courvoisier as indicating a Lorentz-contraction of the earth, in consequence of a movement of the earth towards the light-ether with a speed of 750 km/sec and with an apex at  $A = 60^\circ$ ;  $D = 40^\circ$ . In 1926 one of us (R T) demonstrated—by means of a very much refined repetition of Trouton's and Noble's experiments—that such a Lorentz-contraction is not obtainable electro-dynamically, although 1/2,000,000 of the effect asserted by Courvoisier must have been detected in this way.

As to the existence of the periodic variations of gravity, which Courvoisier observed to be of the order  $dg/g = 3-6 \times 10^{-6}$ , the problem is different. Up to the present we have so little experimental knowledge about gravity that such alterations through cosmic movement of the earth, which undoubtedly exists, cannot be ruled out as impossible.

For these reasons we have tried to study the tidal variations of gravity with all the exactness attainable. We succeeded in increasing the sensitivity and, above all, in reducing the perturbations to such a degree that we are now able to give certain proof of periodic variations of gravity of the order  $dg/g = 10^{-8}$ . We used a bifilar gravimeter which, by suitable choice of dimensions, could be made so sensitive as to record a variation of gravity of  $10^{-7}g$  by a deflexion of about 2-3 mm. In order to prevent the apparatus from being disturbed by changes of atmospheric pressure and humidity, it was sealed up hermetically. In order to avoid vibrations of the ground, it was erected 20 m inside a mountain, in a special room about 25 m below the surface. Registration as well as exact adjustment was done from another room equally isolated. Thus the constancy of temperature during a measuring period of two to three days in each special case amounted to  $1/1000^\circ$ .

Even in the unreduced curves the results obtained did not show any greater variations than about  $2.3 \times 10^{-7}$ , as the order of the tide-effects of the sun and the moon.

Adjusting the curves to sidereal time, during the period of observation up to the present time (7 weeks), it appears that any cosmic influence on gravity cannot exceed the order of about  $10^{-8}g$ . Therefore the variation of gravity asserted by Courvoisier of about  $10^{-6}g$  in consequence of the cosmic movement of the earth does not exist.

On account of their geophysical interest the experiments are to be continued with further improvements.

#### Artefacts of Upper Palaeolithic Facies from Coombe Deposits underlying the Gravels of the Flood Plain

I HAVE lately recorded in these columns<sup>1</sup> the occurrence, south of the Thames, of a 'floor' yielding flint implements of Upper Palaeolithic types and fragments of coarse pottery inter-stratified between Coombe Deposits. The relation of these Coombe Deposits to the Gravels of the Flood Plain has been clearly demonstrated, north of the Thames, by the officers of the Geological Survey.<sup>2</sup> For there the Flood Plain Gravels may be seen overlying the Coombe Deposits, the latter, as at Greenhithe, consisting, in ascending order, of Coombe Rock, coarse gravel, brickearth, and stony loam containing 'rafts' of Coombe Rock.

I am now able to report that this brickearth or 'sandy loam' yields artefacts presenting the same characteristics as do those from the brickearth at Greenhithe.

It is generally accepted that the Magdalenian horizon occurs resting upon the surface of the Flood Plain Gravels, whilst the Solutrian level immediately underlies them,<sup>3</sup> so that on stratigraphical evidence the Greenhithe series must belong to a period even more remote, that is, Aurignacian-Upper Mousterian times.

Through the good offices of the managing director of the Associated Portland Cement Manufacturers Co.,

Ltd, I am conducting an examination of the deposits in question, and the results obtained will be fully published in due course. J. P. T. BURCHELL

#### Diamagnetism of Liquid Mixtures

AN investigation of binary mixtures of diamagnetic substances (one of the substances being water) made in this laboratory has shown a small but definite departure from additivity. The measurements are made with an improved Curie-Cheneveau magnetic balance.<sup>1</sup> In view of the controversy concerning chloroform-acetone mixtures, it has been of interest to examine this system.

The susceptibility-concentration curve is not straight, but any departure from additivity is small—unlike that found by Trew and Spencer.<sup>2</sup> The curve is of the same type as found by Buchner<sup>3</sup> for alcohol-carbon disulphide. There is a flat maximum at equimolecular proportions of the two substances, which shows the diamagnetic susceptibility at this point to be 3.4 per cent higher than additivity. The two minima on the curve show a departure from additivity of the same order. An interesting point is that at the two ends of the curve there is a slight rise in diamagnetism, showing, possibly, molecular dissociation when a small quantity of one liquid is added to the other. The departure from additivity is of the same order, three per cent, as that recorded by Ranganadham,<sup>4</sup> and slightly greater than the two per cent recorded by Buchner.<sup>5</sup>

Trifonov<sup>6</sup> has described a curve for chloroform-acetone concave towards the abscissae. The values found here for the susceptibility of the pure substances are in agreement with other investigators,  $-0.60 \times 10^{-6}$  for acetone, and  $-0.498 \times 10^{-6}$  for chloroform.

#### General Expression for Intensity of Hydrogen Lines.

I HAVE obtained a formula for the total intensity of hydrogen lines in the general case of the transition  $n \rightarrow n'$ . The calculation is based on the principles set out in Sommerfeld's "Wave Mechanics" for the determination of intensities.

The corresponding formulæ for the special cases of  $n' = 1$ ,  $n' = 2$  were published some time ago and are as follows:

$$n' = 1 \quad \frac{2^7(n-1)^{2n-1}}{n(n+1)^{2n+1}}$$

$$n' = 2 \quad \frac{2^6(n-2)^{2n-3}}{n(n+2)^{2n+3}}(3n^2-4)(5n^2-4)$$

I have proved that in the general case the total intensity can be expressed in terms of hypergeometric series in the following form:

$$\frac{2^4(n-n')^{2n+2n'-1}}{n^2n'^2(n+n')^{2n+2n'}} \left\{ \left[ F\left(-n+1, -n', 1, -\frac{4nn'}{(n-n')^2}\right) \right]^2 - \left[ F\left(-n'+1, -n, 1, -\frac{4nn'}{(n-n')^2}\right) \right]^2 \right\}$$

## Research Items.

**Jemdet Nasr**—An account by Mr Ernest Mackay of the archaeology of Jemdet Nasr, Iraq, excavated by the joint Field Museum-Oxford Expedition, is published as *Anthropological Memoirs*, vol 1, No 3, of the Field Museum of Natural History, Chicago. The site, which is situated about fifteen miles north-east of Kish, has now been identified as the ancient Kid-Nun-ki. It consists of a chain of mounds running east-north-east by west-south-west, about 850 metres long by 180 metres wide, the largest mound being roughly 360 metres by 180 metres. The pottery and small antiquities point to a close kinship with the lower levels of Susa and Musyan. Thus, the identity or close similarity in the design of seals of unusual or curious type is explicable only as due to a close connexion, resemblances in methods of working vessels of stone, and in the shapes of several types of pottery, point in the same direction. The painted pottery of Jemdet Nasr is probably rather later than that of Musyan and Susa II, but, on the other hand, it is earlier than the time of Cemetery A, at Kish. Notwithstanding the absence of burials, the objects found prove the existence of an advanced chalcolithic civilisation in Babylonia at an early period. The system of writing had barely emerged from the pictographic stage, but weaving, fishing, agriculture, and pottery-making, in which the inhabitants excelled, were practised. The brick-making is superior to any other in pre-Sargonic times, but in size and shape the bricks are peculiar, being flat instead of plano-convex. Many objects from the Indus valley resemble those of Jemdet Nasr. It is concluded that the inhabitants were not Sumerian but a people conquered by the Sumerians. Prof Langdon, however, relying to a certain extent on later evidence, says it is impossible not to regard them as Sumerians. Taking 3500 B.C. as the date of the destruction of Jemdet Nasr by fire, he thinks occupation of the site may go so far back as 4000 B.C.

**Pneumonia on the Rand**—Pneumonia used to be a formidable disease among the native workers in the Rand mines of South Africa. Following the use of preventive inoculation with pneumococcal vaccine, a marked diminution in the pneumonia incidence resulted. However, we learn from the annual report for 1930 of the South African Institute for Medical Research, that since 1926 this vaccine has apparently been exerting a somewhat lessened influence in preventing the disease, the mortality rate per 1000 population rising from 2.52 in 1926 to 3.60 in 1930. A study of the disease shows that the original strain of infecting pneumococcus, the causative micro-organism, has been largely replaced by other strains against which the original vaccine is less effective, and these new strains are therefore being incorporated in the preventive vaccine. Further, in a large proportion of the cases the pneumococcus is no longer the principal infecting agent, various other micro-organisms taking its place.

**Antlers of Deer**—In a new analysis of the weights of the antlers and the bodies of various species of deer, Prof Julian Huxley carries further the comparison which he began in a former paper (*Proc Zool Soc*, p 820, 1931). In the mass, the 527 adult examples of red deer show that antler-weight bears to body-weight a constant relationship, which includes a steady relative increase in the weight of the antlers. Although a close analysis of individuals, grouped according to the regions of their origin, does not support this result, probably because the examples are extreme, it is confirmed by an examination of regional groups

as a whole. On the other hand, roe deer definitely show a reverse correlation, for in them, judging from 405 wild adult individuals, relative antler-weight decreases with increasing body-weight. When we turn to New Zealand red deer, originally imported from Great Britain, we find exceptionally high relative antler-weights associated with exceptionally heavy body-weights, the former due to the latter, and the latter due to a particularly favourable environment. It seems probable, therefore, that diagnoses of species or sub-species of deer based upon absolute size or relative size of parts cannot be regarded as valid, until it has been shown that the characters selected as diagnostic are genetic and not direct environmental modifications.

**Morphology of the Insect Abdomen**—Under the above title, Dr R. E. Snodgrass of the United States Bureau of Entomology has published an important paper in the *Smithsonian Miscellaneous Collections* for 1931 (vol 85, No 6). It is generally accepted that the insect abdomen consists primarily of twelve segments, the first eleven of which are true somites and the last is the telson. The eighth and ninth segments are the genital segments and bear the gonopods. The genital opening in the female is located, typically, behind the eighth sternum and that of the male behind the ninth. The abdominal appendages of adult and larval insects are serially homologous with the legs and mouth-parts. Each consists of a basis and one or two movable appendicular processes. The basis appears to comprise the coxal and subcoxal regions of a typical appendage. The basis of an abdominal limb usually is incorporated as a plate of the body-wall or united with the sterna. The appendicular processes are very commonly (in the lower insects) the styli or their derivatives, including the claspings organs borne by the male gonopods of the higher insects. The other processes are the gonapophyses. No positive evidence can be adduced from the known facts of anatomy or embryology to establish the homology of either the stylus or gonapophysis. The author inclines to the view that the stylus is the telopodite of the appendage and that the gonapophysis is an endite process of the basis. The main objection to the view that the styli of *Machilis* are the homologues of telopodites is the fact that very similar organs are borne by the thoracic legs. The similarity in the two cases may be misleading, and there seems to be nothing to show that the leg styli are not merely coxal spines resembling in form the abdominal organs bearing the same name.

**Effect of Ultra-Violet Light on Plants**—The production of a glass which allows the passage of ultra-violet light, and the discovery of the antirachitic properties of foods exposed to such radiations, has quickened interest in the effects of these rays on plant life. Experiments have been carried out by W. E. Tottingham and J. G. Moore (*Journal of Agricultural Research*, 43, p 133) to compare the development, and to some extent the composition, of twelve species of economic plants grown under ordinary and vita glass, and to determine whether the use of the latter is of any commercial advantage. The heating effects with vita glass, due to its relatively high transparency to infra-red rays, were largely compensated for by ventilation, but it is realised that some of the results obtained may be attributable to increased temperatures. Marquis wheat developed a darker colour and more erect habit under vita glass, and seed production also benefited. Such differences were not found with

all varieties of wheat, however, nor under all seasonal conditions. Maize and tomato attained a larger size, and in the case of tomato produced more succulent fruit under vita glass, but with both species these larger plants were less hardy towards frost. Soy beans showed an increase in reproductive activity, together with earlier maturation, than plants grown under ordinary glass. As regards the rooting of cuttings, the results were somewhat inconclusive, but the balance was slightly in favour of vita glass in the case of chrysanthemums. The lipid content of the dry matter was in many instances higher in the vita glass plants, but alterations in the protein also occurred in some cases. Although practical application of the results from the commercial point of view seems as yet distinctly limited, there are indications that further investigations along these lines may lead to enhancement of the medicinal potency of plants.

**Cultivation of Mushrooms**—The application of scientific methods to the practice of horticulture proceeds slowly but surely. It is nearly thirty years since the idea of using a pure culture of mushroom spores propagated on sterile manure was introduced. The gardener is now beginning to use it. The introduction of Bulletin No. 34, "Mushroom Growing", by the Ministry of Agriculture and Fisheries, is therefore very opportune, especially as it describes the new processes in simple language and compares them with the old. The preparation of mushroom beds, spawning, 'casing', and other treatment are all dealt with fully, and there is a section on harvesting and marketing. Perhaps the most valuable section of the book is that on diseases and pests. The grower and the student have long waited for some authoritative collection of the information about these subjects, and in the book under review the latest work on the Mycogone disease is summarised. A list of the important works on cultivation and diseases is appended, and will be of great value to the advanced grower and the student.

**Termites in the Formation of Spongy Ironstone in Africa**—Peculiar outcrops of brown ironstone (limonite) of a spongy texture form a feature of the higher regions of Central Africa, particularly of Angola. Livingstone was the first author to direct attention to them so far back as 1857, and white residents in these parts of Africa found them an excellent building material. Dr Malcolm Burr and Mr P. S. Nazaroff, who have recently travelled in Angola, came to the conclusion (*Geol. Mag.*, vol. 68, 1931) that the ironstones present nothing else than subfossil remains of termitaria. The process of ferruginisation of termitaria can be observed even now, being independent from the activities of insects themselves, and is clearly a process of deposition of iron from rain water soaked through soil. When nests are near rocks rich in silica, such as quartzose sandstones, an analogous process of silicification occurs, and the old termitaria are converted into a completely silicified but spongy rock.

**Luminous Phenomena accompanying Earthquakes**—The luminous phenomena of earthquakes have been described as forming the darkest chapter of seismology. Though many writers have been sceptical as to their reality, their existence has been established by Mr K. Musya, who collected about fifteen hundred observations during the Idu earthquake of Nov. 26, 1930 (*Nature*, vol. 128, p. 155). Prof. T. Terada has recently studied about forty examples noticed in Japan (*Earthq. Res. Inst. Bull.*, vol. 9, pp. 225-255, 1931). They have indeed been seen with all recent great earthquakes in that country. In the Idu earthquake, they were observed to a distance of 50 miles east of the epicentre, 68 miles north, and 43 miles

west. At some distance, as in Tokyo, the lights were not unlike sheet lightning. The first flash was seen immediately after the first shock, then three or four others followed at intervals of from one to ten seconds, but the duration of each flash was longer than that of sheet lightning. Close to the epicentre, the light assumed more definite forms, in one case of a straight row of round masses. The colour was usually pale blue or white, and, even in Tokyo, the lights were bright enough to illuminate the objects in a room. Prof. Terada concludes that the phenomena are real, and suggests several causes, such as landslides, to which they may be due.

**Spectra of Negative Ions**—In a paper in the *Zeitschrift für Physik* for Oct. 14, Prof. R. Mecke makes the interesting suggestion that certain band spectra which appear when arcs are run in hydrogen between beryllium or magnesium poles, which had previously been supposed to be emitted from positive ions of the hydrides BeH and MgH, actually come from the negative ions of these compounds. His argument is based on the so-called displacement rule, which applies both to atoms and molecules, and states, for the latter, that molecules which possess the same number of electrons similarly arranged have closely similar spectra. If the bands of magnesium hydride in question were due to the positive ion, they should thus be similar to those of neutral sodium hydride, whereas they are in fact much more like those of neutral aluminium hydride. The beryllium hydride bands likewise resemble those of neutral boron hydride more closely than those of lithium hydride. The evidence presented is so striking that it seems that the only alternative to accepting these spectra as having their origin in molecules which have acquired an extra electron is to reject the displacement rule in relation to molecules. The importance of Prof. Mecke's discovery, if substantiated, is not merely spectroscopic, as it suggests that it may be profitable to investigate the quantum theory and chemical behaviour of negative ions, subjects which have received little attention.

**Crystal Photocells**—The first November number of the *Physikalische Zeitschrift* contains an article by Prof. W. Schottky on the electrical properties of crystals of cuprous oxide held in contact with a metal. This system can be used either as a rectifier for small alternating currents or as a photoelectric device, but whilst the former effect has been widely employed in crystal detectors, it was not known until quite recently that the contact could be disturbed by illumination, and that a current would flow under the influence of light even without an applied potential difference. As is shown in a number of other papers in this and the following number of the same journal, the effect depends both upon temperature and the frequency of the radiation, and it appears that it is primarily due to properties of the crystal rather than to those of the metal. It is not entirely a contact action, since Prof. Schottky has shown that the active layer of crystal is probably not less than  $1\mu$  in thickness, the large free paths for electrons which this calls for are, however, also required by other crystal phenomena, and can be readily accounted for on the wave mechanics.

**Viscosity of Nitrogen at High Pressure**—Some measurements of the viscosity of nitrogen are described by A. Michels and R. O. Gibson in the November number of the *Proceedings of the Royal Society*, which show how the properties of the gas approach those of a liquid when the density of the gas is made large compared with its atmospheric value. The measurements were made by the usual method of forcing gas through a capillary tube, but the apparatus was constructed so that it could be used at pressures

up to 1000 atmospheres. The results demonstrate immediately that the gas law (viscosity is independent of pressure) ceases to be valid at a few atmospheres pressure, the value of the viscosity changing by a factor of 2.5 over the whole range considered. Moreover, at pressures above about three hundred atmospheres the viscosity acquires the typical liquid property of increasing with decreasing temperatures if it is considered as a function of the pressure, although it continues to increase with increase in temperature if it is considered as a function of the density. A theory of the viscosity which has been proposed by Enskog can be tested from the results of these experiments, and leads to values for the diameter of the nitrogen molecule which lie consistently between  $2.9 \times 10^{-8}$  cm and  $3.0 \times 10^{-8}$  cm.

**Crystalline Rubber**—A short communication from E. W. Washburn in the first November number of the *Physical Review* contains the announcement that a group of workers at the United States Bureau of Standards have succeeded in obtaining a well crystallised hydrocarbon from typically colloidal rubber. This has been accomplished by dissolving purified rubber in a suitable solvent to form a dilute solution, and crystallising it out at rather low temperature. A photomicrograph is shown of some crystals which were grown at  $-55^\circ$  from a 0.05 per cent solution in ether. Their melting point has not yet been fixed definitely, but lies between  $-35^\circ$  and  $0^\circ$  C. The molten product has the appearance of ordinary rubber, and contains hydrogen and carbon with an atomic ratio closely eight to five. It has also been found possible to distil the rubber hydrocarbon, but fractionation by this process is relatively slow.

**Stream Lining in Locomotives and Motor Cars.**—Dr O. G. Tietjens contributes an interesting paper on stream line locomotive and car design to the fourth quarterly issue for 1931 of the *Westinghouse International*. He is a research engineer to the company, and his experiments on small locomotives and cars, accurate to the minutest detail, bring out very clearly the importance of stream line design. He finds that an electric locomotive travelling at eighty miles an hour requires five times as much power as when travelling at forty miles an hour. Even higher speeds are contemplated because the competition of aeroplanes and motor cars makes high speeds imperative. In the case of a heavy locomotive and two heavy coaches, stream line design saves thirteen per cent of the power at a speed of 35 miles an hour and thirty-two per cent at a speed of 75 miles an hour. It requires 286 horse-power to drive an interurban street car at a speed of 80 miles an hour. Tests made in the Westinghouse wind tunnel indicate that the same type of car constructed with stream line design can be driven at 80 miles an hour with only 140 horse-power. The power required in the latter case is less than one-half that required in the former. A method is shown of converting the modern American tram-car with its blunt ends, sharp corners, and hundreds of air pockets into a stream line car. A new front and a new rear are given to it, the roof is made smooth, the sides are extended downwards, and the recesses for the windows are eliminated. This reduces the wind resistance to one-third its former value. The new styles of high-speed locomotives and cars will probably soon become common, revolutionising the appearance of the car and greatly increasing its economy and efficiency in operation.

### Astronomical Topics.

**Astronomical Phenomena for January**—Occultation of Pleiades Jan. 18,  $\eta$  Tauri disappears 17<sup>h</sup> 4<sup>m</sup>, reappears 18<sup>h</sup> 3<sup>m</sup>, 27 and 28 Tauri disappear at 17<sup>h</sup> 45<sup>m</sup> and 17<sup>h</sup> 50<sup>m</sup> respectively.

Venus is an evening star, with about five-sixths of the disc illuminated, its meridian passage changes from 14<sup>h</sup> 5<sup>m</sup> to 14<sup>h</sup> 29<sup>m</sup> during the month.

Jupiter is approaching opposition, and is observable for most of the night. Mutual eclipses of the satellites (visible in England) occur on Jan. 3, 5, 7, 10, 12, 23, 24. Details are given in the B. A. A. Handbook.

Neptune is about  $15^\circ$  east of Jupiter, so it is also observable. It reaches opposition late in February.

Minima of Algol, at convenient hours of observation, occur on Jan. 4, at 22<sup>h</sup> 7<sup>m</sup>, Jan. 7, 19<sup>h</sup> 6<sup>m</sup>, Jan. 27, 21<sup>h</sup> 3<sup>m</sup>, Jan. 30, 18<sup>h</sup> 1<sup>m</sup>. Each eclipse begins about 4<sup>h</sup> 7<sup>m</sup> before these times, and ends 4<sup>h</sup> 7<sup>m</sup> after them. The interval between minima is 2<sup>d</sup> 21<sup>h</sup>.

**Moving Pictures of Celestial Objects**—When the cinematograph was invented it was seen that it might be usefully applied to celestial phenomena. Mr Maskelyne took a film of the total solar eclipse of 1900, which was exhibited at the Royal Astronomical Society, and the idea has been repeated at some later eclipses, especially at that of 1927.

The University of Michigan has founded an Observatory, known as the McMath-Hulbert Observatory, at Lake Angelus, Michigan, which devotes itself to the production of moving pictures of celestial phenomena. Vol. 4, No. 4, of the *Publications* of the University gives a description of the methods and results. The driving clock of the equatorial has a very accurate electrical control, there are arrangements for varying the speed of the film within large limits, as the objects photographed range from sunspots to faint variable

stars. There are devices for varying the clock drive, and giving motion in declination for films of moving objects such as the moon. These are also available for correcting for the variation of refraction as the altitude changes, some tables for this purpose are given in the report.

The possibilities of the method were well brought out in a film that was exhibited at the Royal Astronomical Society a few years ago, in which Jupiter was shown in rotation, and the approach of a satellite to the planet was also recorded. It would seem that a comet like that of Morehouse of 1908, in which the tail showed rapid changes, would afford a fruitful field for work with the instrument, unfortunately, such comets are rare.

**'Annuaire' of the Belgrade Observatory for 1932.**—This volume is issued by Dr V. V. Michkovitch, the director of the Observatory, being the fourth of the series. It has the honour of anticipating by a year the British Nautical Almanac in the introduction of the notation terms of short period in the ephemeris of sidereal time at Greenwich midnight, the time is also given to the third decimal of a second. These changes are consequential on the great improvements in clocks that have been made in recent years. The volume also contains ephemerides, at intervals of ten days, of 189 stars from Eichelberger's standard catalogue, these are not contained in other almanacs, and were calculated at Belgrade. Another feature, which must have been troublesome to compile, is a list of the 169 minor planets discovered between Nov. 2, 1929, and June 30, 1931, the dates and discoverers are given, also the dates of subsequent observations, and indications of those for which orbits have been computed.

## Principles of Field Experimentation.

THE science of field experimentation has developed rapidly during the last decade, and its ever-widening importance justified a Rothamsted conference devoted entirely to its principles and technique.<sup>1</sup> As was only fitting, the first paper was contributed by Dr R. A. Fisher, who detailed the three principles of modern field experimentation—replication, randomisation, and local control—and showed how these three are necessary in order to reduce, and to give a valid estimate of, the error which must always loom largely in this type of inquiry. Following this, Dr J. Wishart illustrated the calculations appropriate to randomised blocks and Latin squares, which have proved the most serviceable forms of lay-out.

Later speakers enlarged on a variety of subjects. It is clear from a perusal of the papers that the need is often felt for inquiries carried out at a number of centres simultaneously, so that different conditions of soil and weather may be encountered, and hence that the conclusions may be of general applicability, if each centre adopts the same form of lay-out (though with separate randomisation of treatments) then it is possible to combine all the results in one calculation and attain considerable precision, and still not lose the individuality of the results. Details were given of the methods which experience has shown to be the best for experiments located at a distance from the research station. In these cases a sampling method has proved satisfactory, not only as a means of making developmental studies but also to provide a reliable estimate of the final yield.

Particular cases necessitate special technique. Horticultural experiments introduce difficulty through the longevity of the plants concerned, with the concomitant danger of accident, and the problem of measuring the vigour of the plant. In the case of variety trials, the National Institute of Agricultural Botany still prefers the well-known 'Beaven's half-drill strip' method. The only paper on grass experiments was contributed by Prof. Stapledon, who described the methods adopted at Aberystwyth; he laid much less stress on the statistical adequacy of the technique than on botanical analyses and the problem of how the result should be measured and converted into terms of nutritive value. The papers deal fully

with all the working details, and together they provide a most valuable compendium of experience.

A number of examples of the precision and type of results which may be expected from modern field experiments is contained in the Rothamsted Report for 1930.<sup>2</sup> The majority of problems attacked are manual ones, and the complex lay-outs used give very detailed information. The response of the crop to two or three plant foods, each in varying amounts, can be tested in one and the same experiment, and, if occasion arises, this can be combined with inquiry into the different forms in which any nutrient can be supplied, or the responses of different varieties of the crop plant.

The reader is soon convinced of the necessity for complex experiments, for it is evident in nearly all cases that incomplete inquiry might give misleading results. As an example, it was found that potatoes only responded appreciably to potash and to large doses of nitrogen when a sufficiency of phosphate was supplied, and that superphosphate provoked more than three times as much response in the presence of plenty of nitrogen and potash as it did in the absence of dressings of these two nutrients. Relations of this type appear again and again, making the conclusions difficult to state in a simple manner: there is always a danger in these intricate cases that the reader may 'miss the wood for the trees', but in general the report is admirably and lucidly expressed.

The height of complexity is reached in two rotation experiments which were initiated in 1930: these will yield results year by year, but for their full completion they need twenty years and thirty years, respectively. The Report also contains a brief description of the work proceeding in the laboratory, and summaries of papers recently published by the staff; it is a valuable volume to workers in agriculture and the allied sciences.

## The Coal Measures of Belgium.

IN several Continental countries the geology of the coal measures has for long received great attention. This is especially true of those coalfields where the rocks are highly disturbed and the interpretation of the geological structure is often a matter of great difficulty.

In Belgium a succession of brilliant workers has applied palaeontological methods to the elucidation of the sequences and structures in the coalfields. Lately this work has been carried out under the direction of Prof. A. Renier, of Brussels, whose contributions to the geology of the Carboniferous of Belgium have been widely known for many years. In a recent memoir, Prof. Renier has summarised the development of these investigations, and has given a concise account of his views concerning the mode of deposition of the rocks and of their correlation, while Prof. Pierre Pruvost, of Lille, has contributed to the memoir a very valuable account of the fauna.\*

\* Considérations sur la stratigraphie du terrain houiller de la Belgique, par Armand Renier, La Faune continentale du terrain houiller de la Belgique, par Pierre Pruvost. *Mém. Mus. Roy. d'Hist. Nat. de Belg.*, No. 44, 1931.

Prof. Renier asserts that in the coal measures of Belgium the floor of every seam is full of the footlets of *Stigmara*. The plant remains of these fossil soils are of very monotonous aspect, *Stigmara ficoides* being present at every horizon throughout the sequence. Renier emphasises that the tracing and recording of such fossil soils, even when they are, locally, not overlain by coal seams, is of great assistance in the investigation of the strata. This is in marked contrast with the general practice in many mining areas in Britain, where frequently there have been no records of any of the strata passed through excepting the coal seams.

Renier directs attention to the wide lateral extent of many coal seams, while at least one marine bed in the coal measures he recognises in areas so far apart as the Pas de Calais, Holland, and Westphalia. This wide extent of at least some beds in the Upper Carboniferous strongly supports the view that there was at times continuous deposition over wide areas. The views formerly held by some geologists regarding the deposition of the coal measures in small isolated basins,

more or less co-extensive with the present coalfields, receive no support from Renier's work

In contrast with the uniformity of the floors of the coal seams, the roofs yield extremely varied faunas and floras. These have been examined and recorded with great precision. Renier quotes approvingly the words of Crépin, who laid down two rules for palaeontologists working on the coal measures so long ago as 1878. Palaeontologists, he advised, should never confine their researches to material collected from the rubbish tips of collieries, but should themselves descend the mines and study the Carboniferous vegetation *in situ*, further, they ought not to leave the collecting exclusively to workmen and others ignorant of the science, but to undertake some of the labours themselves.

The neglect of this advice—not only in Belgium—led for many years to serious errors in regard to the palaeontology of the coal measures. Thus, Prof. Renier shows that certain palaeontologists who have studied the coal measures of Belgium since Crépin's time based their conclusions almost entirely on museum collections, and decided that the flora was uniform in character from top to bottom of the sequence, recent work, on the other hand, based on the actual examination of each horizon, has made it clear that distinct floras can be recognised and used both in the identification of seams and in the correlation of the coal measures over western Europe.

Prof. Pruvost's account of the non-marine faunas

makes a fitting sequel to his monumental work on the faunas of the coal measures of the north of France. A beautiful series of plates is devoted chiefly to the fossil insects and other arthropods and to the fishes. A number of remarkable fossils is described, and this part of the memoir will be indispensable to all students of coal measure palaeontology. It is much to be regretted that no illustrations of any of the Mollusca are included (except in relation to their supposed borings), the Mollusca are much more frequent than other fossil animals at most horizons, and Pruvost relies on them to a great extent in his correlation.

Pruvost is not prepared, however, to accept any of the refinements in nomenclature which have been made in recent years. To a large extent he has followed the late Dr. Wheelton Hind, who was very conservative (and sometimes, unfortunately, rather inaccurate) in his interpretation of these species. But whereas even the latter was willing to recognise some twenty-five species of non-marine lamellibranchs in the coal measures of Belgium, Pruvost admits no more than twenty. In his 'lumping' of species he places *Anthracomya librata* Wright as a synonym of *Carbonicola similis* Brown, and *Naradites elongata* Hind as a synonym of *Anthracomya philipsi* Will. It is probable that his discrimination of the faunas is much more precise than the nomenclature which he uses, but his method must make it difficult for other palaeontologists to make full use of his labours.

A. E. TRUEMAN

### Dyestuffs and Enzymes.

MANY dyes and related compounds have a specific toxic effect on certain micro-organisms which has been utilised in the treatment of the diseases caused by them. The mode of action of the dyestuff is not known, but it is probable that it poisons some particular system in the cell, without which the latter cannot carry on its metabolic activities.

Some recent researches by J. H. Quastel on the action of dyes upon enzymes may throw light not only on the nature of the toxic effect, but also on the constitution of the enzymes employed (*Biochem Jour*, vol. 25, p. 629, 1931 (with A. H. M. Wheatley), and *ibid.*, vol. 25, pp. 898 and 1121, 1931). In the first paper it was found that basic, but not acid, dyes inhibited the oxygen uptake by *B. Coli* in the presence of glucose, lactate, succinate, and formate. The degrees of inhibition varied both with the dye and the substrate used, so that the effect could not be due to a general lethal action. Since it is the basic dyes which are active, it appears that the cell dehydrogenases are essentially acidic in character, but basicity is not the only factor in toxicity, since the basic Bismarck brown has little action. The inhibitory action of the dye was less marked in phosphate than in veronal buffer. Similar results were obtained with muscle enzymes, but no inhibition was observed with any dye when brain tissue was used, probably because the dye failed to reach the enzyme.

In the second paper, the behaviour of fumarase from micro-organisms or from brain or red-blood cells

was studied. This enzyme converts fumarate to l-malate, which can be estimated polarimetrically. It was found that both acid and basic dyes were toxic, but a marked specificity was apparent, of the former, the Congo red series was the most toxic, of the latter, the triphenylmethane series. It was also observed that fumarate combines with its enzyme and prevents the combination, and hence the toxic action, of both acid and basic dyes, that proteins exert a protective action, and that the protective action of phosphates is less than in the case of the dehydrogenases.

The most recent experiments have been carried out with certain naphthylaminedisulphonic acids and fumarase, after observing that trypan red and Bayer 205, like Congo red and trypan blue, are toxic. None of the six acids tested were toxic, nor were their first *s*-carbamide derivatives. The second and especially the third *s*-carbamide derivatives were, however, very toxic, that is, the *s*-carbamides of *m*-aminobenzoyl-naphthylaminedisulphonic acid and of *m*-aminobenzoyl-*m*-aminobenzoylnaphthylamine-disulphonic acid. The importance of this observation lies in the fact that there is a definite, though not strict, parallelism between the toxic action of these carbamides on fumarase and their trypanocidal potency, as determined by Balaban and King. It is possible that this method of investigating the toxicity of dyestuffs on enzymes may prove suitable for preliminary tests in the preparation of compounds likely to be of chemotherapeutic value.

### Carbonisation of Coal.

GRATE expectations have been placed upon coal carbonisation at low temperatures as a source of motor spirit. Fuel Research Technical Paper No. 34 (H.M.S.O., 6d net), on the "Light Spirits from the Low Temperature Carbonisation of Coal", shows that the experience with benzole production cannot be directly transferred to low temperature products.

The proportion of tar acids and unsaturated compounds is higher, necessitating greater consumption of chemicals in refining. The refined products were found by actual tests in petrol engines to be good motor fuels at least equal, when fresh, to commercial petrol. They still contained considerable quantities of unsaturated compounds which were liable to polymerise.

on storage and they show increased gum and peroxide formation, accompanied by decrease in the highest useful compression ratio (H U C R). The report suggests the need for caution in assessing the value of low temperature processes as sources of motor fuel.

The pioneers of low temperature carbonisation seemed to take it for granted that the tars and oils produced would find markets ready for their absorption. Even now, this idea is still widespread. Experience brought disillusion, and it became clear that only after long research could one expect to develop uses for these novel products. Among other institutions the Fuel Research Station has studied systematically the influence of conditions on the general character of the tars and liquors. A more detailed chemical study of the tars was undertaken by the National Chemical Laboratory at Teddington with the view of discovering, if possible, new industrial applications for these products.

Much of this work has been published in periodicals and is now included in a Fuel Research Technical Paper No. 32, entitled "A Study of the Tars and Oils Produced from Coal" (H M S O., 2s net). This is in four parts—statistics, the treatment of low temperature tars from a commercial retort, the carbonisation of three British coals at varying temperatures, and

the influence of temperature on the properties of tars. Perusal leads to the conclusion that in the development of low temperature processes too much capital has been spent on large scale plant, and too little on laboratory investigation of the chemistry of the processes and their products.

One branch of the work of the Fuel Research Board is the physical and chemical survey of national coal resources, which now covers practically the whole of the British coalfields. The reports hitherto published have dealt with the detailed survey of seams of coal. Paper No. 20, which has just appeared (H M S O., 1s 3d net), entitled "The Yorkshire, Nottinghamshire and Derbyshire Coalfield, Analysis of Commercial Grades of Coal, Part I", breaks new ground by giving the analyses of the commercial products of about forty important collieries in the district. It can scarcely be doubted that the information will be of great use to those concerned with the selection and purchase of coal, whether at home or abroad. The report should also be of great value to the collieries concerned, and will excite envy in other industries not so fortunate as to have their products so examined and certified. Perhaps the most striking impression which the reader can gain from the figures is the high quality of the fuel marketed in this area. Most of the samples contain less than five per cent of ash.

### High Speed Flying.

AT an evening discourse delivered before members of the British Association on Sept. 29, Mr. H. E. Wimperis, Director of Scientific Research to the Air Ministry, gave an interesting résumé of accomplishments, and speculations as to future advances, in high speed flying. The very high accelerations set up have given rise to various problems, both structural in the aircraft and physiological in the occupant. A rate of three times that of gravity can be obtained in starting by the use of catapults. These are necessary for obtaining the minimum speed for flight for fast machines in a reasonable space. It is interesting to note that this rate of increase of speed is about a hundred times that of a steam-engined railway train. Even greater accelerations are experienced in curved flight—up to five times gravity—and as the machine is only designed to withstand a load of 8g, care has to be exercised, in making rapid turns of small radius, not to approach this. The centrifugal force on the pilot in such turns drives the blood from his brain to the more distensible parts of his body, and this is accompanied by a loss of sight, although not of mental clarity.

Such high speed machines are necessarily built as seaplanes, as it is impossible to make aerodromes with sufficiently flat surfaces, or large enough, to allow of reaching the very high minimum flying speed with safety. Even on smooth water, handling requires

considerable skill, as the angle at which the floats will leave the water due to hydro-planing is greater than the machine can maintain when it becomes air borne. Another peculiar trouble arises from the fact that at speeds of above 360 m.p.h. the rush of air actually heats a body passing through it, instead of cooling it. This complicates the question of cooling both the engine and the pilot's cockpit.

With regard to future progress, while there is no theoretical limit to speeds higher than 407.5 m.p.h., the present record, there are many practical difficulties to be overcome. Better streamlining would give up to another 60 m.p.h. for the same power, but some excrescences which spoil this, such as the undercarriage, tail, etc., appear to be inevitable. At the velocity of sound, namely, about 700 m.p.h., there is a doubling of the head resistance, which would appear to be an insurmountable barrier to aircraft of the present form, but with other aerodynamic outlooks this may be passed.

Another method of reducing resistance would be to fly at altitudes of, say, 100,000 feet, where the reduced density of the air would offer less resistance to motion. This would probably need some form of rocket propulsion, as the present-day engine would not function without a sufficient supply of oxygen, neither would the propeller have enough bite on the thin air to transmit the necessary thrust.

### Hardening of Metals in a Magnetic Field.

MR. E. G. HERBERT, of Manchester, contributed a paper to the Royal Society in January 1931 and two articles to *Metalurgia* in May and June of last year on the hardening of metals in a magnetic field. The Royal Society paper describes the fluctuations in the hardness of steel, duralumin, and brass caused by rotation in a magnetic field. Mr. Herbert shows that the time element is an important factor in the hardening produced magnetically. He has found that the hardness changes are sometimes very rapid, and in hard steel, freshly treated, changes may sometimes be observed from minute to minute.

Later research has shown that the effect produced in steel by the magnetic treatment is periodic in character, generally extending over many hours subsequent to treatment. In some experiments there were a sequence of six alternate increases and decreases of hardness occupying gradually lengthening periods of time. It was found that when a rotary magnetic field was used the maximum hardening effect could be produced by a single turn in the magnetic field at a suitable temperature followed by a period of ageing. The cloud-burst process of hardening by steel ball bombardment could be superimposed on the

rotating field method, the processes being apparently independent of one another

Mr Herbert adopts as a provisional theory that the rotating magnetic field gives rise to a fluctuation of a periodic character in the systems of electrons, which in turn causes periodic fluctuations in molecular cohesion. A very interesting possibility of a practical nature follows from these investigations, namely, the stabilisation of the metal at a selected phase in the fluctuations set up mechanically, magnetically, or otherwise. For example, the stabilisation of steel wire in a condition characterised by greatly increased ductility with undiminished tensile strength.

In *World Power* for October, Mr Herbert describes some work in connexion with high-speed tools. At present the results obtained seem very anomalous, in some cases the magnetic field has a hardening effect on the metals experimented on, and in other cases it softens them. The results suggest that the magnetic effects have been merely superimposed on the normal age-hardening process. They may be quite different in character. A softening magnetic process added to age hardening might be expected to slow down the hardening process, while a hardening magnetic treatment added to the normal hardening might be expected to accelerate it. It was observed that an increase of hardness equivalent to an increase of 13 per cent on the Brinell scale was induced in high-speed steel by a single turn of the magnetic field, occupying about a minute and applied at a temperature of only 100° C. Such a treatment could easily be given to finished tools of the most complicated character as well as to drills, sawblades, and dies in which a high degree of hardness is desirable. It is probable that further experiments, especially as to what is the best temperature to employ, will give even better results. As no metal hitherto subjected to magnetic treatment has failed to react, it is possible that these effects are common to all metals. In the non-magnetic metals the hardness changes hitherto produced have been relatively slight, but research in this direction seems very promising. It has been suggested that these changes may not be confined to metallic or even to inorganic substances.

### University and Educational Intelligence.

LONDON.—Dr F. A. von Hayek has been appointed for the session 1931–32 to the Tooke chair of economic science and statistics tenable at the London School of Economics.

The following titles have been conferred in respect of posts held at the Colleges indicated: *Professor*—Dr Charles Singer (history of medicine, University College), Mr E. F. D. Witchell (mechanical engineering, Imperial College—City and Guilds College) *Reader*—Mr R. J. Tabor (botany, Imperial College—Royal College of Science), Dr W. G. Bickley (mathematics, Imperial College—City and Guilds College), Dr G. F. J. Temple (mathematics, Imperial College—Royal College of Science), Mr B. W. Holman (mining, Imperial College—Royal School of Mines), Dr Herbert Dingle (physics, Imperial College—Royal College of Science), Dr H. S. Gregory (physics, Imperial College—Royal College of Science), Dr S. G. Paine (plant bacteriology, Imperial College—Royal College of Science), Mr J. P. Ross (surgery, St Bartholomew's Hospital Medical College), Dr L. C. Martin (technical optics, Imperial College—Royal College of Science), Dr Elizabeth A. Fraser (zoology, University College).

The title of emeritus professor in the University has been conferred on the following.—Prof E. J. Garwood, on his retirement from the Yates-Goldsmid chair of

geology at University College, Prof C. Spearman, on his retirement from the chair of psychology at University College, Prof W. E. Dalby, on his retirement from the chair of civil and mechanical engineering at the Imperial College—City and Guilds College.

The degree of D.Sc. in biochemistry has been conferred on Bireschandra Guha for a thesis entitled "Investigations on the Factors of the Vitamin B Complex and on the Newer Factors necessary for the Normal Nutrition of the Rat" (*Brit. Med. Jour.*, 1931, and *Biochem. Jour.*, 1931).

For the session 1931–32, the Department of Coal Gas and Fuel Industries with Metallurgy of the University of Leeds has arranged a series of evening courses, with practical work. The courses comprise studies in the manufacture of coal gas, refractory materials, the coke fire, and metallurgy. Further information can be obtained from the Registrar, University, Leeds.

THE professional education of teachers in the United States of America during the past ten years is reviewed in *Bulletin*, No. 30, 1931, of the Office of Education, Washington. One of the most striking changes brought to notice is in the relationship between the demand for and supply of certificated teachers. The number of students in training for teaching increased from 135,435 in 1919–20 to 274,348 in 1927–28, the number of students completing one-, two-, and three-year curricula during the same time increased from 21,012 to 49,627, whilst those graduating after a four-year course increased from 1296 to 8179. The oversupply of teachers in many places and the overcrowding in a few teachers' training institutions have led to the raising of the standard of requirements for admission to teacher-training courses. There has been also rapid progress in raising standards of certification. The average number of students per training institution has grown from 439 to 877, necessitating better facilities for their social and physical welfare. Of the strictly professional courses, student teaching is coming to be recognised as one of the most important, and it is much more frequently provided than formerly, but probably fifty per cent of teachers enter upon their duties without having been through such a course. Training colleges are increasingly concerning themselves with the careers of their graduates, and recognising an obligation not only to see them placed but also to help them in overcoming their inevitable difficulties during the first year or two of teaching.

COMMONWEALTH Fund fellowships will be available early in 1932 for British students who desire to continue their studies in American universities. Last year there were 121 candidates (99 men and 22 women) for ordinary and Dominion fellowships, and 29 fellowships were granted, 56 candidates applied for service fellowships (open to those in government service only), and 6 appointments were made. Of the 35 fellows appointed, 20 came from faculties of science. These fellowships are available to research graduates and also to students who have just taken their first degree. There is no fixed stipend attached to a fellowship, but each is of the approximate annual value of 3000 dollars. Each fellowship includes provision for an equipment allowance of 200 dollars, and a travel allowance, tuition fees, etc., 150 dollars per month for living expenses, allowance for travel during the Christmas recess, and allowance for three months' travel (which is compulsory) at the end of the first academic year. A fellowship is tenable for two years, with possible extension to a third year. There is very little limitation to the subject of study which a fellow may choose. Applications for fellowships must be

sent to the authorities of the college or university of which the candidate is, or has been, a member, and must reach the Secretary by Feb 8, 1932. Further information can be obtained from the Secretary, Commonwealth Fund Fellowships, 35 Portman Square, London, W 1

### Calendar of Geographical Exploration.

Jan 1, 1841 — The Antarctic and the Ice-Barrier

Under the direction of Capt J Clark Ross, R N, an expedition consisting of two ships, the *Erebus* and the *Terror*, crossed the antarctic circle to prosecute surveys for the British Government. From the point of view of geographical discovery, this was the most fruitful of all antarctic voyages. Ross was an experienced arctic traveller and had located the north magnetic pole in 1831. Under his direction, ships for the first time deliberately pushed their way into the pack ice. This ice, previously thought to stretch on indefinitely to the remote land, proved to be a belt about a hundred miles wide, and the *Erebus* and *Terror* passed through it to open waters now known as Ross Sea. By Jan 11, Ross had sighted the rocky coast of South Victoria Land and had noted the Admiralty Range running north-west along the coast, and a further range going southwards. Unable to reach the mainland, he landed on Possession Island and claimed the newly discovered land for Britain. Later he sighted an active and an extinct volcano, named respectively *Erebus* and *Terror* after the vessels. The great ice barrier, with peaks 200 ft - 300 ft in height and extending for 250 miles, seen for the first time, checked his farther southward progress. Like the Frenchman, Dumont d'Urville, who had set out from Hobart on Jan 1 of the previous year, he was compelled to give up the dream of reaching the south magnetic pole, though he penetrated nearer to it than any previous explorer.

Sixty-one years later, on Jan 1, 1902, the *Discovery*, with Lieut R F Scott, R N, as its commander, and with E H Shackleton, R N R, as one of its lieutenants, met the pack ice and thence penetrated to Ross Sea. The ice-barrier had retreated 30 miles since Ross was there. Scott found that the land which Ross had believed to be east of the ice-barrier, but which he had cautiously charted as an "appearance of land", was plainly visible, its higher summits rising 2000 ft - 3000 ft. above the sea. It was further discovered that McMurdo Bay, charted by Ross, was in reality the opening of a strait leading southwards between Ross Island and the mainland. Mt *Erebus* proved to be not on the mainland, but on what is now mapped as Ross Island.

Jan 2, 1923 — The Libyan Desert

A M Hassanain Bey left Sollum, a small port on the Mediterranean near the western frontier of Egypt, on his difficult journey southward through the Libyan desert to Darfur. As a result of his work important new facts about the orography and geology of the region were recorded. His discovery of the rock basin oases of Arkenu and Owenat makes possible further desert travel in the still unexplored regions of the Libyan desert. His route linked up with Tilho's explorations in the French Sudan and confirmed the latter's conclusion that Lake Chad has no possible drainage outlet in an easterly direction.

Jan 7, 1830 — The Murray River

Charles Sturt launched a boat on the Murrumbidgee and sailed thence along the Murray to the sea. He had previously discovered a portion of the Darling River, this second "bold and desperate" venture solved the nature of the inland river drainage of south-eastern Australia.

### Societies and Academies.

#### CAMBRIDGE

Philosophical Society, Nov 23 — T M Lowry and C B Allsopp. Refractive dispersion and the problem of 'optical exaltation'. A thin film of liquid is placed between the plates of a quartz etalon and the interference bands are focused on the slit of a spectrograph. The order of the interference bands is deduced from pairs of refractive indices determined with a refractometer. Refractive indices can then be deduced to four places of decimals in the visible or ultra-violet regions up to the limit of transparency of the film — T M Lowry and H K Gore. Optical rotatory power of vapours. Measurements have been made of the rotatory dispersion of camphor and of camphorquinone as vapour and in solution. In the region of absorption, camphor gives a curve with a composite maximum. This is explained by the composite character of the ketonic absorption band, as evidenced by the fact that the curve of circular dichroism covers a smaller range of wave-lengths than the absorption curve — T M Lowry and H Hudson. Absorption and circular dichroism of optically active substances. Measurements have been made of the absorption, circular dichroism, and rotatory dispersion of a series of bornyl xanthates. The two absorption bands are optically active but of opposite sign. The curve of circular dichroism therefore crosses the axis, as is observed experimentally in the methyl xanthate — C P Snow. Fine structure of absorption bands in crystals. The absorption bands of compounds of the rare earths in the crystalline state show well-marked discontinuities similar to the line spectra of the atoms. This has recently been shown to be due to the 'shielding' of an inner incomplete electronic group throughout the series of the rare earths. There is a marked sharpening of the lines when the crystals are cooled to liquid air temperature and below. Reasons for this have been discussed (see Snow and Rawlins, *NATURE*, 125, p 349, 1930) — R G W Norrish. Predissociation in relation to photochemical activity. A large group of primary photochemical effects may be correlated with the condition known as predissociation in the molecular absorption spectrum. With aldehydes and ketones, however, although photodecomposition coincides with predissociation, it is difficult to envisage the mechanism of the change, since the chemical data for some fifteen examples indicate that no free radicals are produced. It would appear that molecular rearrangement involving more than one bond occurs within the molecule.

#### PARIS

Academy of Sciences, Nov 23 — H Vincent and L Velluz. The immunogenic properties of the duodosalicylic cryptotoxin. From experiments on guinea-pigs, it has been proved that the duodosalicylic cryptotoxin, the preparation of which is given, is capable of rapidly conferring immunity against pure tetanus toxin. This cryptotoxin neutralises the tetanus toxin, the latter not being destroyed but converted into a harmless complex. This non-toxic complex rapidly immunises animals — C Sauvageau. The third kind of plurilocular organs of *Ectocarpus secundus* — Paul Montel. The upper limit of the moduli of the zeros of polynomials — Eduard Čech. The theory of dimensions — Maurice Janet. The minimum of the ratio of certain integrals — J A Lappo-Dandilevski. The decomposition of the normal integral matrix of a system of linear differential equations and the construction of the primitive

matrix—Jacques Devisme Some partial differential equations—Abramesco The Leja factor of uniform convergence of a series of polynomials—R Mazet The unity of the solution of problems of friction—Constantin Woronetz Lines of slip on a cylinder—J Baurand Periodic waves at the surface of water—Louis Bréguet Aerodynamic suspension of the aerial vehicle—J Dufay and R Gindre α-Herculis, a variable star of very small amplitude Previous observations on this variable star have given discordant results The photometer used in these observations gives an accuracy of about a hundredth of a magnitude, and 136 photometric comparisons were made The results are given in the form of a curve, showing a period of 22 days The form of the curve corresponds to a double star with eclipses—F Link and J Devaux The photometric and actinometric study of the moon during the eclipse of Sept 26, 1931—Paul Woog, Jean Givaudon, and Mlle Emilie Ganster Neutralising varnishes, properties of orientation of their superficial molecules Molecular polishing By the application of certain varnish coatings, lubricating oil can be prevented from spreading out over solid surfaces The composition and mode of treatment of such a varnish are given, and the theory of the process is discussed—Guy Emschwiller The mechanism of the photolysis of the alkyl iodides Either of the two theories, dissociation or activation, affords an explanation of the phenomena observed in the photolysis of the alkyl iodides—D K Yovanovitch and P Savitch The calorimetric study of the absorption of the γ-rays of radium Instead of the usual ionisation method, the authors use a microcalorimeter A null method is used, the heat produced by the radium being balanced by electrical heating Curves are given showing the heat developed by absorption in lead, silver, and copper—Mlle M Th François The anomalies observed when using benzene and nitrobenzene in cryoscopy It is usually held that benzene and nitrobenzene possess two *K* constants, one normal and applying to most organic substances, the other abnormal (hydroxyl compounds), practically half of the first The author's experiments cited do not confirm this—Augustin Boutaric and Charles Tournour The study of colloidal solutions by the polarisation of the light diffused by them For extremely small spherical particles, the theory of Lord Rayleigh shows that the diffused light should be totally polarised if the particles increase in size, the proportion of polarised light should be reduced Hence the study of the polarisation gives interesting information concerning the changes in a colloidal solution approaching the condition of flocculation—G Austerweil The preparation and purification of salts by the use of zeolites—J Golse The reduction of mercuric cyanide by tin in the presence of certain metallic salts Although tin is without action upon neutral solutions of mercuric cyanide, when sodium chloride (or certain other salts named) is added, hydrocyanic acid is set free, and the mercury is reduced to metal in accordance with the equation

—Ernest Kahane The possibility of destroying considerable quantities of organic substances by means of perchloric acid After a preliminary treatment with a mixture of nitric and sulphuric acids, and driving off water and excess of nitric acid, the perchloric acid is added drop by drop, the liquid being maintained at 190° C The oxidation is rapid and complete—E M Bellet The reaction between esters and alcohols in a slightly alkaline medium—Andre Kling and Daniel Florentin The mode of action of hydro-

genating and mixed catalysts in the hydrogenating cracking of phenols—Dalloni The geological constitution of Tibesti The pre-Cambrian substratum—H Le Breton The coast-line of post-neolithic age in Xu-Nghé and in Trois-Quang of the north (Annam, French Indo-China)—Chadefaud The morphological signification of the stigma of the zoospores and the zoogametes in the Heterokontæ and Phaeophyceæ—Théodore de Camargo The influence of the potash-nitrogen ratio on the development of the coffee plant during the first period of growth—Emile F Terroine and Mlle Germaine Boy The distribution of the nitrogen compounds of the urine in the minimum endogenous nitrogen consumption and in protein nutrition the problem of existence and of the magnitude of the albuminoid reserves—Mlle Marcelle Lapique Chronaxy of subordination in an invertebrate—Mme. H Heldt Observations on the laying, fertilisation, and the first stages of development of the egg in *Penaeus carinatus*—Maurice Piettre Remarks on the physical state of the calcium phosphates in milk the fractionation of their micelles leads to the existence of free calcium caseinate and of a calcium phosphate compound By physical means, centrifugation, freezing, and especially by dialysis against water, glycerol or saccharose, increasing proportions of calcium phosphate can be separated, and by using sodium citrate a casein can be obtained containing only traces of lime Hence it is concluded that in milk the colloidal lime exists as the triphosphate—Bordier A new helioactinometer The amount of iodine set free from a solution of iodoform in chloroform under the influence of the solar photochemical rays is taken as a measure of the light received—J André Thomas The production of tumours of sarcomatous appearance in the annelid *Nereis diversicolor* by inoculation with *Bacterium tumefaciens*

#### GENEVA

Society of Physics and Natural History, Nov 5—P Rossier The spectral sensibility of photographic plates The author gives an analytical expression for the sensibility curve of the photographic plates used at the Geneva Observatory This expression allows the study in some detail of certain applications of these plates to astronomical photometry—E Briner, H Paillard, and R Zurcher Attempts at supplying an internal combustion motor with air mixed with ozone In spite of the very low concentrations (about 1 in 10,000) in which it was introduced into the gas, ozone produced 'knocking' On account of the peroxidising properties of ozone, the effect noted appears to support the theory attributing detonating combustion to the formation of very unstable intermediate peroxides—R Wavre The small vibrations of liquid stars The author applies the 'uniform method' to the study of the small movements of stars composed of a nucleus and a fluid envelope Assuming the solid nucleus, he arrives at the results of Lord Kelvin concerning the oceanic tides The contrary assumption of a liquid nucleus is a new problem which he has succeeded in solving He develops also the influence of the terrestrial tide on the oceanic tide and gives the principal results

#### LENINGRAD

Academy of Sciences—*Comptes rendus*, No 7, 1931—N Tagejeva and F Starik The radium content of the petroliferous waters of Tchelenen island The water contains from  $6.75 \times 10^{-11}$  to  $4.37 \times 10^{-11}$  gm of radium in 100 cc of water—L Kurbatov The radioactivity of the mineral water of Nefte-dagh and Tchelenen—V Baranov and L Kurbatov The radium

content of the petroliferous waters in the Grozny district. The radium content of water in July-September proved to be considerably less than in March of the same year—L Komlev. The radium content in the water of oil wells in the Novo-Grozny district. Beginning with July 1929, a marked reduction on the radium content was observed, although the general chemical content of the water remained practically unchanged—V Ignatovskij. Functions which are orthogonal to the hypogeometrical series (1).

*Comptes rendus*, No 8, 1931.—A Fersman (1) A geochemical diagram of the Chibim mountains—(2) The geochemistry of gold—D Priamishnikov. The formation of ammonia during the reduction of nitrates by the higher plants. Normal plants absorb ammonia more energetically than nitrates—A Popov. A new genus of fish, *Davidjordania* (Zoaridae), from the Pacific Ocean. *Lycenchelys lacertinus* Pavl is made the type of a new genus, to which *L ornatus* Sold and *L pæcilumen* Jord and Fowl are also referred. *Lycenchelys brachyrhynchus* Schm belongs to the genus *Hadropareia*, and *L fasciatus* Schm is a synonym of *Lycodes fasciatus* Schm—V Scherbina. Chemical constitution of the nepheline from the Chibim mountains.

## SYDNEY

Royal Society of New South Wales, Sept 2—H Finemore and C B. Cox. The amount of hydrocyanic acid in *sorghum* sudan grass and some hybrids. *Sorghum* contains a higher amount of prussic acid than has been hitherto recorded, and it loses this acid as the plant develops, but even on cutting and wilting the young plant by no means becomes innocuous. Of the results obtained, it was shown that the variety *Feteritis* is the most poisonous. Contrary to opinions held in some quarters, it was found that sudan grass contains an appreciable amount of prussic acid—F R Morrison and R Grant. A contribution to the chemistry of the fruit obtained from the White Cedar tree (*Melha Azedarach*, L var *australasica* C DC; Syn *Melha australasica*, A Juss) growing in New South Wales, with notes on its reputed toxicity. Proximate analyses of the fruit were obtained from trees growing at Grafton and Dubbo, New South Wales, respectively. The ripe fruit obtained from Grafton trees contains a sticky pulp, consisting of a starchy meal, a resin, an oil, and dextrose, with acid and other water-soluble substances. Feeding tests using guinea-pigs showed the Grafton fruit to be non-toxic, whilst fruit from trees growing at Dubbo and Parramatta, respectively, proved in some cases to contain a toxic constituent, which was found to be present in the resinous portion of the fruit. A very small quantity of basic material was extracted from an ether solution of the resin by means of 0.5 per cent sulphuric acid solution. Neither the basic extract nor the resin from which it was extracted produced toxic symptoms when administered alone, but a mixture of both produced fatal results.

Oct 7—J C Earl and C H Wilson. The condensation of  $\alpha$ - $\beta$  dibromocarboxylic acids with benzene in the presence of aluminium halides. Cinnamic acid dibromide and crotonic acid dibromide when treated with aluminium chloride and benzene give the corresponding derivatives of dihydrophenanthrene. By the use of ferric chloride or aluminium bromide, instead of aluminium chloride, linking between the two phenyl nuclei does not take place,  $\alpha\beta$ -tri-phenylpropionic acid and  $\alpha\beta$ -diphenylbutyric acid being formed from the cinnamic and crotonic acid dibromides respectively.

No 3244, VOL 129]

## Diary of Societies.

## FRIDAY, JANUARY 1

ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 3.30—E R Jarrett. Christmas Juvenile Lecture on Architecture.  
ROYAL PHOTOGRAPHIC SOCIETY, at 7.  
JUNIOR INSTITUTION OF ENGINEERS, at 7.30.

## SATURDAY, JANUARY 2

ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Sir William Bragg. The Universe of Light (Christmas Lectures) (3).  
Light and Colour (1).

## MONDAY, JANUARY 4

VICTORIA INSTITUTE (at Central Buildings, Westminster), at 4.  
INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales—Liverpool—Centre) (at Liverpool University), at 7.  
INSTITUTION OF RUBBER INDUSTRY (at Engineers' Club, Manchester), at 7.  
WOLVERHAMPTON AND DISTRICT ENGINEERING SOCIETY (at Victoria Hotel, Wolverhampton), at 7.30.  
BRITISH KINEMATOGRAPH SOCIETY (at Gaumont Theatre), at 7.45.  
ROYAL INSTITUTE OF BRITISH ARCHITECTS, at 8.  
SOCIETY OF CHEMICAL INDUSTRY (London Section) (at Chemical Society), at 8.

## TUESDAY, JANUARY 5

ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Sir William Bragg. The Universe of Light (Christmas Lectures) (4).  
Light and Colour (2).  
INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at Engineers' Club, Manchester), at 7.  
INSTITUTION OF AUTOMOBILE ENGINEERS (at Royal Society of Arts), at 7.45.

## WEDNESDAY, JANUARY 6

ROYAL SOCIETY OF ARTS, at 3—Prof E N da Costa Andrade. The Vacuum, or the Importance of Nothing at All (Dr Mann Juvenile Lectures) (1).  
INSTITUTION OF ELECTRICAL ENGINEERS (Wireless Section), at 6.  
INSTITUTION OF ELECTRICAL ENGINEERS (Tees-Side Sub-Centre) (at Cleveland Technical Institute, Middlesbrough), at 7.  
INSTITUTION OF HEATING AND VENTILATING ENGINEERS (at 20 Hart Street, W C 1), at 7.  
INSTITUTION OF AUTOMOBILE ENGINEERS (at Queen's Hotel, Birmingham), at 7.30.  
INSTITUTE OF BREWING (North of England Section) (at Midland Hotel, Manchester).  
ROYAL MICROSCOPICAL SOCIETY (Biological Section) (at B M A House, Tavistock Square).

## THURSDAY, JANUARY 7

ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Sir William Bragg. The Universe of Light (Christmas Lectures) (5).  
Light from the Sky.  
LINNEAN SOCIETY OF LONDON, at 5.  
INSTITUTION OF CIVIL ENGINEERS (Birmingham and District Association) (at Chamber of Commerce, Birmingham), at 6.  
INSTITUTION OF ELECTRICAL ENGINEERS, at 6.  
INSTITUTION OF AUTOMOBILE ENGINEERS (Bristol Centre) (at Merchant Venturers' Technical College, Bristol), at 7.  
SOCIETY OF CHEMICAL INDUSTRY (Bristol Section) (at Bristol University), at 7.30.  
ROYAL SOCIETY OF MEDICINE (Tropical Diseases and Parasitology Section), at 8.

## FRIDAY, JANUARY 8.

ROYAL GEOGRAPHICAL SOCIETY, at 3.30—Mrs Murray Chapman. Through Lapland in Winter with Sledge and Reindeer (Christmas Lecture for Young People).

ROYAL SOCIETY OF ARTS (Indian Section), at 4 30  
 ROYAL ASTRONOMICAL SOCIETY, at 5  
 ROYAL ANTHROPOLOGICAL INSTITUTE (Human Biology Research Committee), at 5 30  
 MALACOLOGICAL SOCIETY OF LONDON (at Linnean Society), at 6  
 INSTITUTION OF MECHANICAL ENGINEERS, at 6—S B Freeman Modern Types of Propelling Machinery for Mercantile Marine Use (Thomas Lowe Gray Lecture)  
 INSTITUTION OF ELECTRICAL ENGINEERS (Meter and Instrument Section), at 7  
 ILLUMINATING ENGINEERING SOCIETY (at Royal Society of Arts), at 7  
 JUNIOR INSTITUTION OF ENGINEERS, at 7 30  
 GEOLOGISTS' ASSOCIATION (at University College), at 7 30  
 —Dr W F Whittard An Expedition to East Greenland, 1929 (Lecture)  
 SOCIETY OF CHEMICAL INDUSTRY (Newcastle Section) (jointly with Institute of Chemistry) (at Newcastle-upon-Tyne)

#### SATURDAY, JANUARY 9

ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Sir William Bragg The Universe of Light (Christmas Lectures) (6) Light from the Sun and the Stars

#### Public Lectures.

#### MONDAY, JANUARY 4

ROYAL GEOGRAPHICAL SOCIETY, at 3 30—The President South and East (Christmas Lecture for Young People)

#### WEDNESDAY, JANUARY 6

UNIVERSITY COLLEGE, at 3—Sir Richard Gregory, Bt Comets and Shooting Stars  
 IMPERIAL COLLEGE OF SCIENCE AND TECHNOLOGY, at 5 30  
 —Dr T M Finlay The Evolution of Landscape (Swiney Lectures) (1) (Succeeding Lectures on Jan 8, 11, 13, 15, 18, 20, 22, 25, 27, 29, and Feb 1)  
 BELFAST MUSEUM AND ART GALLERY, at 8—Mrs H Richardson Costume and History

#### Conferences.

#### JANUARY 4 AND 5

MATHEMATICAL ASSOCIATION (at London Day Training College)

Monday, Jan 4, at 3 30—Sir Arthur Eddington The Decline of Determinism (Presidential Address)

At 5—Prof S Brodetsky Modern Dynamics in Astronomy, Relativity, and Quantum Theory

Tuesday, Jan 5, at 10 A M—Discussion on The Report of the Association of University Teachers on Entrance Tests and Initial Degrees

At 11 15 A M—Dr S Verblunsky The Foundations of Mathematics

At 12 15—Prof A Lodge Interpolation by Central Differences

At 2 30—G Frecheville The Application of Mathematical Methods to Research Work in Agricultural Economics

At 3 30—Discussion on Calculus and Co-ordinate Geometry at the School Certificate Stage, with special reference to the Additional Mathematics Syllabus of the Joint Matriculation Board of the Northern Universities

#### JANUARY 4 TO 11

CONFERENCE OF EDUCATIONAL ASSOCIATIONS (at University College)

Monday, Jan 4, at 3—Sir William Rothenstein Presidential Address

At 5—Dr E Miller The Difficult Child Sociological v Individual Interpretations (Lecture) (British Psychological Society—Education Section)

Tuesday, Jan 5, at 2 30—Discussion on The Film as an

Instrument of Humane Education (University London Animal Welfare Society)

At 3—J H Whitehouse Public Schools and the Public Life (Lecture) (Society for Experiment and Research in Education)

Wednesday, Jan 6, at 3—Sir Richard Gregory, Bt Comets and Shooting Stars (Lecture) (School Natural Study Union)

At 5 30—Prof D Laurie Biology in Schools (Lecture) (Association of Assistant Mistresses)

Thursday, Jan 7, at 2 30—Mrs C B S Hodson The Feasibility of including Simple Biology and Heredity Teaching in the School Curricula (Lecture) (Eugenic Society)

Friday, Jan 8, at 2—Discussion of Physical Education in Schools (Medical Officers of Schools Association)

#### JANUARY 5 TO 7

EXHIBITION OF SCIENTIFIC INSTRUMENTS AND APPARATUS (at Imperial College of Science and Technology), 3 to 5 and 7 to 10

Tuesday, Jan 5, at 8—C C Paterson Photocells The Valves which operate by Light (Lecture)

Wednesday, Jan 6, at 8—T Smith Photographs Shutter and their Properties (Lecture)

Thursday, Jan 7, at 8—Sir Oliver Lodge Reminiscences (Lecture)

#### JANUARY 6 TO 11

GEOGRAPHICAL ASSOCIATION (at London School of Economics)

Wednesday, Jan 6, at 9 30 A M—Opening of Publishers' Exhibition and Address by Miss E H McLean

At 11 A M—Discussion between the Historical Association and the Geographical Association What is Historical Geography?

At 2—Sir Leslie Mackenzie A Health Administrator's Attitude to Geography (Presidential Address)

At 5 30—S A S Hozayen The Expansion of the Arabs and their Contribution to Geography (Lecture)

Thursday, Jan 7, at 11 A M—Mrs H Ormsby The Part played by the Limestones in the Human Geography of France (Lecture)

At 12—J Fairgrieve Demonstration Lesson with Films

At 2—Demonstration of Amateur Films

At 3—J Fairgrieve The Use of Films in Teaching

At 5—Prof P F Kendall How Britain became an Island (Lantern Lecture)

Friday, Jan 8, at 10 30 A M—Brigadier H S L Winter botham New Developments of the 1" Map (Lantern Lecture)

At 11 30 A M—Prof Gerhard Schott The Humboldt Current in Relation to Land and Sea Conditions on the Peruvian Coast (Lantern Lecture)

At 2 45—Discussion on The Difficulties of using the Lantern in Primary Schools

Discussion on The Scope and Content of the Geography of the 'rest of the world' in the First School Certificate Examination

## Science and Politics.

SOME months ago the British Science Guild committed itself to the important task of producing, on behalf of the scientific community, a volume which would assist the people of Great Britain, including its statesmen, politicians, administrators, financiers, and industrialists, to realise the value of the contributions which science has already made to our progress as a nation, and the potentialities of science in the evolution of a better order of society. This volume, when completed, will contain a survey of the results hitherto obtained by the application of science in all departments of national life: a survey of our existing industries and a comparison between them and the corresponding industries of certain other countries; a survey of the possible effects of the further application of science to our older basic industries and our newer industries, the possibility of creating new industries, and finally, how our industrial development is affected by legislative restrictions, our system of taxation, our banking and financial methods, the attitude of professional and manual workers' organisations towards the application of science, and political theory.

The compilation of such a work is a task to which those scientific workers who are conscious that they are also citizens must apply themselves, as much for the education of the scientific community as for the body politic. It cannot be denied that the scientific community has lost opportunity after opportunity since the War to take a more active part in the framing of national and imperial policy. The temptation leading its members into a narrow professionalism of outlook militates against their effectiveness in any sphere outside their own. They rightly charge others with the neglect of science, but the failure of the nation adequately to appreciate science and the scientific outlook is to some extent attributable to their own indifference to public opinion, to their own failure to make their work intelligible to the uninitiated, and to their scorn of, or at least indifference to, the efforts of some of their own fellow-workers to interpret their work to the lay community.

The pity is that this habit of mind is inculcated in most undergraduates studying science in our universities. Instead of being encouraged to regard a training in science as an indispensable qualification for the responsibilities of leadership in any field of national activity, they are led to believe that their studies in any particular branch of science unfit them for any occupations other than

those of teacher, research worker, or technologist in that branch. The consequence is that few graduates in science in Great Britain seek administrative or commercial posts with the large industrial and commercial corporations, take up posts with the banks, financial houses, or insurance companies, few apply for entry to the home or overseas administrative civil services—practically none find an outlet in the administrative services of local government bodies—they rarely turn their attention to the Bar or politics, or the diplomatic and consular services. In other words, although our civilisation is based on science, those trained in science leave to those who have not had this advantage most of the key positions in industry, finance, politics, and the various central and local government services of the Empire. May not this be the root cause of our present parlous economic position?

It will take time to remedy this state of affairs. Nevertheless, it must be remedied, and it is well that a start should be made now, when the nation is ready to listen to any authoritative diagnosis of its troubles and to give careful consideration to any suggested remedy or even palliative for them. It is dissatisfied with its statesmen, politicians, financiers, and industrialists. It has a religious faith in the efficacy of science. It is not impossible that the whole force of public opinion could be mobilised in support of a well-thought-out and comprehensive scheme, prepared by men of science, economists, and industrialists, for the effective utilisation of the resources of the British Empire. The first essential is that this scheme should be in the main the contribution of scientific workers with an interest in the economic and social implications of their work, and industrialists and others with a sincere belief in science and understanding of the scientific outlook. Another essential is that it should represent the collective views of the scientific community.

In his recent article on "National Needs" in *NATURE* of Dec. 26, "H. E. A." suggests that the Royal Society is the only body which can undertake this responsibility. We, however, do not hold this view. The Royal Society is not constituted to engage in the campaign required, or even to act as a focus. Having been consulted by the central Government for many years past, and being in receipt of Government grants, the Society is not in the position of independence essential for the consideration or criticism of public offices or affairs. Moreover, the fellowship of the Royal Society is not sufficiently catholic

to embrace many of those whose co-operation is essential for the production of a practical scheme for national and imperial reorganisation and reconstruction. Nevertheless, it is to be hoped that the Royal Society will be able to assist in this great task, whatever body undertakes it.

It is true that the British Science Guild by itself, because of the character of its membership, could produce a scheme which would command the attention of the country. But it is obvious that a scheme produced by and published with the authority of duly accredited representatives of all the various scientific and technical societies in Great Britain would carry more weight. The British Science Guild would welcome their co-operation, first, because it would show that the scientific societies had not lost all contact with the realities of modern life, and secondly, that they realised the need for a body to perform certain necessary and important tasks for which they lack both the funds and the machinery to undertake themselves individually. The industrialists have the Federation of British Industries as well as associations in each industry to safeguard their interests and, whenever circumstances demand, to express their collective views to Government and the general public. The same is true of the banks, financial houses, and trade unions. Industrialists, financiers, traders, and trade unions see to it that their interests are well represented in Parliament. Up to now, the scientific community has neither built up a strong representative body nor collectively assisted any of its members to enter the House of Commons, where the influence of ten or twelve members qualified to speak for science and backed by science would be disproportionately great in comparison with their numerical strength.

We suggest ten or twelve representatives of the scientific interest advisedly. One member cannot undertake the whole responsibility. On practically every subject of discussion in Parliament science has an important contribution to make, a point of view which should be expressed in the public way for which Parliament provides facilities, and which ministers of the Crown cannot ignore in the same way as they can ignore advice tendered through their departmental officials. Apart altogether from those matters which directly affect the scientific community, such as grants for research and for the training of research students, the efficiency of State scientific departments and the status of their expert staffs, patent law, the future of industrial research associations, where

the emphasis is on the duty of the general community to science, there is a wide range of subjects on which the emphasis is on the duty and service of science to the general community. These subjects include the effect of the maldistribution of gold and silver on our present trade and financial position, the question of the restriction of imports of manufactured goods and agricultural products, housing, health services, disarmament, imperial development (with which is linked the questions of emigration to the Dominions and the acclimatisation of whites in our tropical dependencies), the need for factory legislation in connexion with dangerous trades, and the development of our home resources, both industrial and agricultural.

When Parliament meets again in February, much of its time will be occupied in discussing the estimates of the various departments of State. Here, again, a critical survey by a group of representatives of science would be invaluable. That it will not be made is certain, first, because there is no such group in Parliament, and secondly, because the scientific societies have been slow to respond to the invitation of the British Science Guild to create a body competent to collect the necessary data as the basis of such activities.

### Ant-Lions and Worm-Lions

*Demons of the Dust: a Study in Insect Behaviour*

By Prof William Morton Wheeler Pp xviii + 378 (London Kegan Paul and Co, Ltd, n.d.) 21s net

A STUDY of parallel development in behaviour between the worm-lions and ant-lions must be interesting and important. "A legless maggot and a six-legged Neuropteran larva equipped with powerful sucking mandibles, carry on, though by somewhat different methods, one and the same industry for the purpose of obtaining their food." These are termed respectively the worm- and ant-lions. Their feeding is predatory, craters being made in loose sand, a larva lying partially hidden at the basal point of each. Ants and other small wanderers which stumble into these pits, slide in the sand and are at once grasped and sucked.

The ant-lion is a classical beast and is probably identical with the Myrmecoleon of Job, being referred to in the medieval commentaries thereon. Albert the Great (c. 1250) gave a description based on his own observations, and Poupert an adequate account in 1704. The anthropomorphism evidently attracted authors, for Vallisneri brings into a dialogue between Malpighi and Pliny in the

Netherworld (c. 1700) the habits of the larva and its transformation to the imago. The Abbé Pluche in his "Spectacle de la Nature" also adopts the same form and humanises the ant-lion as combining "the traits of an expert huntsman, an able geometrician and a miscreant with barbarous and bloody inclinations." This gave the ant-lion a reputation, which attracted the great personalities of zoology of the eighteenth century.

Réaumur's memoir was followed by Bonnet's, both founded on the living insects, the latter described how the larva pushes pebbles, many times its own weight, out of its funnel, placing the tip of its abdomen under them and backing. The pit is made by the larva marking a groove of the requisite diameter by moving backwards and tossing the sand from the inner border of the same to the outside by means of its head and closed jaws. The direction is clockwise or counter-clockwise. A cone is left in the centre, the process being continued within the circle, usually in the same direction, until the crater is completed. But even in the same species a direct method of digging has been observed, so that "the insect cannot be regarded as a pure reflex automaton, especially as a like variability also characterises all the remaining activities of its feeding cycle." The prey is automatically precipitated to the almost hidden larva, it is seized, smothered in sand, bitten and paralysed, partially digested by the injected saliva, and its juices imbibed, lastly, its carcass is thrown out, and the crater is repaired before the ant-lion resumes its quiescent wait for the next prey.

The Mediterranean worm-lion is the maggot of a fly and was known to Poupert, it formed the subject of the last of Réaumur's memoirs. This together with a report by De Geer on specimens sent by Réaumur to the Queen of Sweden are advantageously reprinted (translated) in appendices to the present volume. The further accounts of the worm-lions are mainly a product of the present century and are largely illuminated by our author's own observations on the animals, which he reared himself. Here, as throughout the book, the advance made is shown to be due partially to wider knowledge, especially of the fauna of the sands, and partially to improved technique, backed by the broader considerations of modern biology. Wheeler obtained his insects in the Balearic Islands and, feeding them mainly on white ants, transported them to Boston, where the last flies emerged about a year later. The pupal period extends through two or three weeks, the insect lying below the bottom of its burrow, in this stage it is sticky,

so that sand grains adhere firmly to it. Unfortunately, the emergent flies were delicate and would not mate, so that the eggs and first larval stage are still unknown.

A California subalpine species, the Sierra worm-lion, was described by Wheeler in 1918, but the reference is lacking. It occurs up to 9000 ft., at this height in quite unsheltered situations, whereas at 4000-5000 ft. in the Yosemite it is always in dust that is rarely wetted and little exposed to the sun's rays, the maggot evidently not being strongly thermotactic. Hundreds of larvæ were transported to Harvard and reared. Their pronounced annulation and marked mobility of the anterior segments form a useful comparison with similar features in many of the leeches. It would, however, be too technical to refer here to the excellent morphological descriptions given of this and of the other insects considered—especially, perhaps, that of the stomach and gut, the physiology of which is also of great interest. They lead to the general conclusion that the singular characters of this worm-lion “developed in specific adaptation to its own peculiar environment”, critical adjustment here is in the larval stage, whereas in the Hymenoptera this is best seen in the imago. The study of the behaviour and development of the larvæ in Wheeler's laboratory and the deductions therefrom form a delightfully interesting chapter, of high scientific value and of literary excellence.

While the above species of worm-lions and two others from the western States and Cuba belong to *Vermileo*, another allied genus, *Lampromyia*, is found in Africa. One species was collected by Wheeler in the Canary Islands, being transported as usual to his laboratory, fed, observed, and reared. Later, he was sent live specimens from Sarawak of yet a third genus, which he terms the “worm-tiger”.

The concluding chapter summarises the whole question of the astonishing conformity of behaviour between the larvæ of the ant-lion and of the worm-lion, the differences to us appearing much less striking, though fully emphasised in the text. The behaviour pattern of either insect is so complicated that its evolution could only have been built up very gradually. This appears likely, the ant-lions being partially traced back to Permian and the worm-lions to Jurassic forms. The present distribution of both and other considerations lead to the suggestion that they developed their larval behaviour in some semi-arid Mesozoic period. The term ‘lochesis’ is suggested for the ambushing of prey by many organisms instead of actively seeking it. We certainly would not apply this term to

plants, and would hesitate to do so to most marine animals other than Antennulata, especially sedentary colonial forms. The discussion which follows is illuminating, as emphasising the rôle of the environment in the behaviour of animals. The insect here makes a portion of its surroundings into a collecting crater, while many animals use flowers and other objects as traps, in the case of web-formers, we find ‘exteriorised’ portions of an animal's own body employed to the same end.

As compared with Wheeler's previous works, we may say of this book, as he himself remarks of Réaumur, that it “reveals no impairment of his unusual powers of observation”. Indeed, it shows development, mature literary form, and such a nice biological delight in his pets that he interests his readers in every phase of his subject. A book like this does much to break down the arbitrary and most undesirable separation of ‘entomology’ from ‘zoology’, we hold that the greatest curse from which zoology suffers is the dividing off from it of many ‘ologies’, which, it is imagined, can be pursued by professional scientific men without an understanding of basal facts relating to living matter.

J STANLEY GARDINER

#### Organic Chemistry. General and Specialised.

- (1) *The Principles of Organic Chemistry* By Prof. James F. Norris (International Chemical Series) Third edition Pp. xii + 595 (New York McGraw-Hill Book Co., Inc., London: McGraw-Hill Publishing Co., Ltd., 1931) 15s. net.
- (2) *Theoretische Grundlagen der organischen Chemie.* Von Prof. Walter Huckel. Band 1 Pp. xi + 410. 24 gold marks. Band 2 Pp. iv + 352. 20 gold marks. (Leipzig Akademische Verlagsgesellschaft m. b. H., 1931.)
- (3) *Die Polysaccharide* Von Hans Pringsheim. Dritte vollständig veränderte Auflage Pp. ix + 393 (Berlin Julius Springer, 1931) 26.80 gold marks.
- (4) *Die Alkaloide eine Monographie der natürlichen Basen* Von Winterstein. Zweite neue bearbeitete Auflage von Dr. Georg Trier. Teil 2 Pp. xi + 357-1061 (Berlin Gebrüder Borntraeger, 1931) 42 gold marks.

(1) **P**ROF J. F. NORRIS is well known to organic chemists as an original investigator and a teacher of wide experience. His mode of introduction to the fundamental principles of the science is unusual, but deserving of consideration by other

teachers of the subject. Probably many teachers would prefer an arrangement different from that adopted, and, indeed, Prof Norris's arrangement involves at times a considerable amount of reference to different parts of the book in connexion with the treatment of particular classes of compounds or individual substances. Few other authors of such a textbook have indicated more clearly the wide ambit of organic chemistry and its bearing on our knowledge of biological processes, and although the book may be regarded as somewhat encyclopædic for beginners, the perspective between different branches is well maintained.

It is unusual for such a textbook to be lacking in illustrations and to contain so few references by name to outstanding investigators. The absence of illustrations renders some descriptions rather lengthy and somewhat vague, and although the name of an investigator means little when the personality is obscured, it may be a convenient 'peg' on which to hang facts or principles. A unique feature of the book is the chapter devoted to the identification of organic compounds and the determination of their structure. This is extremely well done and is valuable for systematising the reader's knowledge. The book is attractively written, and has so many things to recommend it that it is almost a shock to find that the nomenclature used for the simple monosaccharides is not more systematic.

(2) Prof W Huckel's "Theoretical Principles" is deserving of the closest study as a statement by an authority who has carefully considered the present conceptions and their development both as regards structure and the mechanism of reaction of organic compounds. The treatment of some parts of the subject is highly condensed, but the author has kept his treatise within reasonable dimensions without omitting the discussion of any modern method for investigating the structure and behaviour of organic substances.

A comprehensive criticism of the author's opinions would involve far more space than can be available in an ordinary review. It is certain that these will be criticised, but this criticism will serve to stimulate further investigation on organic compounds by methods which have been made available in recent years. Already, Huckel's views are being quoted in original communications, and the author is to be congratulated on the production of a comprehensive work of outstanding value to present-day organic chemistry.

(3) During the last seven years the developments in carbohydrate chemistry have been fundamentally

important, primarily as a result of W N Haworth's investigations of the simple sugars, and the third edition of Prof Pringsheim's monograph is a useful résumé of our present knowledge of the more complex portion of this section of organic chemistry. The book is well printed and the formulæ particularly well set out.

The simple polysaccharides from the maltose type to the tetrasaccharides are discussed for the most part in tabular form in the first section of the book, the remainder being devoted to the complex polysaccharides, cellulose, starches, etc. It might be pointed out that the references to the literature on the constitution of the simple polysaccharides in the tabular list are not complete in themselves, but are supplemented by others appearing later in the same section of the book. This indicates that the book requires detailed study, otherwise it might appear that important references had been omitted. A little fuller critical treatment in this section would have been advantageous.

The second section contains an exhaustive treatment of cellulose, starches, and inulin with regard to the properties of their different forms and their bacterial and fermentative decomposition, and, after discussing modern methods for the determination of the constitution of these highly complex substances, present views regarding the actual constitutions are particularly well stated. Although the book is somewhat expensive—a not unusual feature of modern German works on chemistry—it is a most useful contribution to the literature of the subject.

(4) All workers in alkaloid chemistry must be familiar with Dr Trier's comprehensive and excellent monograph generally known as Winterstein and Trier's "Die Alkaloide". The special portion of this second part contains a well-written account of the history, the determination of the chemical constitution, the biochemistry, pharmacology, toxicology, the therapeutic uses, etc., of the lupin and lobelia alkaloids and those of the indole, quinoline, and isoquinoline groups which include the alkaloids of the strychnine, morphine, papaverine, and cryptopine groups. The author's connotation of the term 'alkaloid' has made it possible for him to include an account of the two interesting bacterial colouring matters, pyocyanin and prodigiosin, together with the ptomaines, vitamins, and hormones. In view of the rapid growth of our knowledge of the vitamins and hormones in consequence of the work of so many investigators at the present time, this section will become out of date very rapidly.

The general portion deals with such general problems as the relationship between constitution and sources of the alkaloids, the relationship between pharmacological action and chemical constitution, the methods of analysis and outlines of methods of determination of the constitution of the alkaloids. The value of the book depends not only on the detailed information it contains, but also on the many indications as to materials which need further investigation both by the chemist and the pharmacologist

C S GIBSON

### The Philosophy of Science.

*Du cheminement de la pensée* Par Émile Meyerson  
(Bibliothèque de philosophie contemporaine)  
Tome 1 Pp xxvii+294 Tome 2 Pp 295-716  
Tome 3 Pp 717-1036 (Paris Félix Alcan, 1931) 130 francs

THE last work of M. Émile Meyerson is a noble completion of those which have preceded it. It is marked by the same thoroughness and impartiality in examining the views of others, the same steadiness in presenting his own, the same confidence in the progress of science and the growing unity of thought. Coming last, and being written with due care and leisure, it contains a full review of the philosophical bearing of relativity and the quantum theory, as well as a recapitulation of the argument of the earlier books. The third volume of this work, which consists entirely of extracts from the writers whom he quotes from all ages, is alone well worth the trouble of publication, and the whole three volumes, sold at little more than £1 (gold currency!), are indispensable for anyone interested in the nature and history of scientific thinking. The excellent French, the invariable politeness, the flashes of humour, make the book as delightful as it is enlightening.

The general thesis remains the same as that developed in "L'explication dans la Science" and "Identité et Réalité". The author sums it himself in a phrase which deserves to live: "L'Homme sait le divers et veut l'identique". This essential process of seeking constantly fresh identifications in a real which presses upon us in growing richness and variety, is traced from the Greeks to the present time.

The book is so convincing that it is worth while to examine in some detail the reasons why it leaves this impression on the mind. The main reason is that M. Meyerson never allows himself to take absolutely one side in any of the sharp oppositions

of thought which have marked the 'cheminement de la pensée' throughout the ages. He is frankly a dualist, and shows how at every stage of thought a fresh combination of the real of experience is offered to the inquiring mind of man, and at each stage the mind adds something to it from its own creating and synthesising power. Thus, even in the simplest form of identification, Kant's numerical 'equation',  $5+7=12$ , something is added, the result is not a pure tautology. So, with an algebraical identity,  $(a+b)(a-b)=a^2-b^2$ , there is much more than mere identity.

Something new is gained from every experience. The case is even clearer in the origins of geometry. Meyerson has no doubts, and leaves none in our minds, that the foundation of this science is the work of the creative genius of the Greeks, and he goes on to show that the Aristotelian syllogism, unjustly condemned as tautological by a dominant modern school, conforms also to his ideal of actually enlarging our thought in the guise of expressing another identity. Thought never advances either by pure extension or pure analysis. At each step we take in some new fact and then proceed to see its essential connexion with an identity which we have previously established. No general idea, whether in mathematics or in non-mathematical thinking, is purely a collection of objects or of notions 'externally brought together'. In every case we imply, or seek for, some coherence of the attributes in the essence or nature of the genus or general idea.

This is the act of identification which M. Meyerson finds to be common to all forms of scientific thinking. All thought is movement and all phenomena are change. What M. Meyerson means by 'identity' is really the result of the constant effort of the mind to seize the common element in the passing show. The difference between mathematical and other kinds of reasoning is not in essence but in the fact that in mathematics the identification is more precise.

The other fundamental aspect of the subject is the fact that there must be identity between diverse minds before any general judgment can be passed on the diverse real. *Nolenti non fit demonstratio*. On this side again we may go back to Aristotle, who declared that both in the syllogism and other forms of reasoning there must be assent as well as formal demonstration. M. Meyerson's attitude throughout is the best possible for inducing this frame of mind in others. He always seeks first for what he can accept in the views of those whom he criticises. He scarcely

mentions anyone from whom we may not gain some enlightenment, and the total effect of this method of approach in the gradual unfolding of the human spirit in the history of science is most inspiring. He rightly regrets the limited interest taken in this supreme subject, and the highest recommendation of the book is that it is bound to send some of its readers to study the material on which it is based.

Apart from this, it contains the most admirable and convincing criticism—convincing because so temperate as well as searching—of Bergson, Bradley, Brunschwig, and many other workers in the field.

F S MARVIN

### Short Reviews.

*A History of Geographical Discovery and Exploration*. By J N L Baker (Harrap's New Geographical Series). Pp 544 (London, Bombay and Sydney: George G Harrap and Co, Ltd, 1931). 12s 6d net.

MR. BAKER'S pioneer effort to survey the whole field of geographical discovery throughout the centuries fills a long-felt need. There is an embarrassing wealth of original accounts of voyages of discovery, and there are a few outstanding studies of particular periods or regions. With remarkable skill and accuracy the author has here gathered together all the essentials of our knowledge of the obtaining of the data on which modern charts and maps are based. A short bibliographical study precedes the volume, for each chapter a main source list is given and, in addition, there are numerous text references to authorities. The author frequently points out that the more spectacular voyages were by no means always the most fruitful in scientific results, his thoughtful appraisal of the ultimate geographical importance of many little-known voyages should help to stimulate the student's critical faculty.

There are fifty line maps, some of them arranged on a folder method which makes it easy to consult them when reading other pages. The frontispiece shows the world according to Behaim (1492) superimposed upon a map of the world as known to-day.

In a brief summary the author directs attention to an important, but too often forgotten, fact—the very small proportion of the world which has been scientifically surveyed in detail. Students need to be reminded that the printed map frequently gives a deceptive suggestion that all is known of a region. S. Obruchev's work in north-east Siberia (1926) shows how misleading are all available maps of that region. A further edition of this volume will inevitably be called for, since it is indispensable for all serious students of geography, in it we hope there may be added a map indicating the extent of fully surveyed country. The publishers have done geography a service by issuing so full and detailed a book at such a reasonable price.

*The Sturge Collection: an Illustrated Selection of Plants from Britain bequeathed in 1919 by William Allen Sturge*. By Reginald A. Smith. Pp xii + 136 + 12 plates (London: British Museum, 1931). 25s net.

IN 1919 the archaeological collections of the British Museum were much enriched by the bequest of the large and valuable collections of the late Dr. Allen Sturge. He had amassed specimens on his visits to England from Nice, where he was in practice, and on his retirement, when he settled at Icklingham in Suffolk, he became an assiduous collector, with the assistance of his wife, in that happy hunting ground of the student of the stone age implement. To his own collections he added others by purchase from time to time, those belonging to Canon Greenwell, Allen Brown, and Worthington Smith, among others, passing into his possession. Nor was his interest confined solely to the specimens from Britain, which are dealt with in the work under notice. The implements from other parts of the world which he collected have gone to the Ethnographical Department of the British Museum.

In this descriptive catalogue of a selection from the British implements now in the Department of British and Mediæval Antiquities, geographical distribution has been followed in preference to typology, in accordance with the arrangement for exhibition purposes. Dr. Sturge's home at Icklingham has been taken as the centre, and the various sites are grouped according to their distance from it. The list is very fully illustrated, so that in addition to being a tribute to the testator's generosity, which is its primary purpose, it is also an album which, while indicating the richness of the bequest, may also serve, as its author hopes, to fix types and nomenclature for the benefit of the student. There is no discussion, but ample references are made to the relevant literature.

*Spencer's Last Journey: being the Journal of an Expedition to Tierra del Fuego by the late Sir Baldwin Spencer, with a Memoir*. Edited by R. R. Marett and T. K. Penniman. With Contributions by Sir James Frazer and H. Balfour. Pp xii + 153 + 14 plates (Oxford: Clarendon Press, London: Oxford University Press, 1931). 12s 6d net.

A SENSE of tragedy is inseparable from this volume commemorating Baldwin Spencer's last journey, the expedition to Tierra del Fuego in 1929, on which he died. Although he himself would, no doubt, have chosen to end his life in harness, his work was unfinished. His intercourse with the few Yahgans with whom he came into touch was not without result. He collected implements, which are described by Mr. Balfour in an appendix, and he recorded some of their kinship terms and a small vocabulary which will be of service to science, but anthropologists must forgo the light of his unrivalled first-hand knowledge on the problem which has been raised by the suggested affinities between Fuegian and Australian culture.

Baldwin Spencer's journal, which is here printed in full, and his note-books exemplify the care with

which he worked. They show, too, the skilfully exercised powers of observation of Nature which always lay behind his work, and were unimpaired with the passing of years. Sir James Frazer's eloquent appreciation of Baldwin Spencer's work, which places it in true perspective as a unique record of which time will enhance the value, Dr Marett's sympathetic memoir, and Miss Jean Hamilton's account of the last few days before his death and her perilous journey in conveying his body to its last resting-place, make this a volume which all admirers of Spencer's work will treasure.

*Nucleic Acids*. By P. A. Levene and Lawrence W. Bass. (American Chemical Society Monograph Series, No. 56.) Pp. 337. (New York: The Chemical Catalog Co., Inc., 1931.) 4.50 dollars.

SPECIALIST knowledge grows apace, though sometimes at great difficulty, along the paths of error and controversy, by the combined labours of many workers. This is particularly true of the chemistry of the nucleic acids, about which there are already two monographs by English and German authors, now supplemented by one from an American writer whose own researches in the field have been of prime importance. The plan adopted by Drs. Levene and Bass is to deal first with the components of the nucleic acids, then with the nucleosides and nucleotides, and finally with the nucleic acids and the enzymes which decompose them. In part the subject is treated in historical sequence; there are ample references and two indexes.

The nucleic acids are established in structure as phosphoric esters of glucosides, the organic radical being a pyrimidine or purine derivative. By their very structure such complex compounds are liable to reversible intramolecular rearrangements which it is fair to assume will alter both their chemical and biological function.

Chemists are beginning to gain an idea of the importance of phosphorus compounds in the living cell, especially as factors in facilitating molecular rearrangements and transformations as witnessed by their function in fermentation and in muscular changes. It is probable that we are on the eve of striking advances in our interpretation of intracellular reactions, and it is essential that the whole existing knowledge of the subject should be adequately presented in monograph form, as is done here.

*Plane Trigonometry*. By B. B. Bagı. Pp. vii + 248. (Dharwar: The Author, Reddy Housing Society, 1931.) n.p.

THIS volume has been written essentially to suit conditions in Indian colleges. The author claims that his treatment has greater vigour and comprehensiveness than is to be found in many of the existing textbooks written for use in English schools. It is a little difficult to see precisely wherein the real divergence lies, for the book begins, as usual, with the measurement of angles, the use of signs in geometry and orthogonal projection. It then covers the customary groundwork up to the properties of triangles and quadrilaterals. There are

also short chapters on finite series and products, elimination and limits. It seems strange to divorce elimination from equations, yet the latter comes roughly in the middle of the book, whilst the former is relegated to Chap. xx—the last but one!

The relations between the sides and angles of a triangle are established by a uniform method founded upon projection, whilst in solving triangles the older method of using tabular logarithms is used to avoid the negative characteristic. Seven-figure tables with the necessary work in proportional parts are employed, and on p. 126 a reproduction of a page from Chambers's "Tables" is given.

There are many examples taken from recent examination papers fully worked out to illustrate the text, and each chapter ends with a good selection for the student to solve.

*Il passato e il presente delle principali teorie geometriche, storia e bibliografia*. Per Prof. Gino Loria. Quarta edizione totalmente rifatta. Pp. xxii + 467. (Padova: Casa Editrice Dott. Antonio Milani, 1931.) 60 lire.

THE first edition of Prof. Loria's treatise on the history and bibliography of geometry was an expansion of a course of lectures delivered at Genoa in 1886. After an introductory chapter on geometry up to 1850, there followed eleven more dealing respectively with higher plane curves, surfaces, space curves, differential geometry, analysis situs, line geometry, correspondences and transformations, enumerative geometry, non-Euclidean geometry, hyperspace, and miscellaneous topics. This was translated into German and Polish. The second edition added references up to 1896. The fourth edition is doubled in size, the extra matter forming a second part, on a similar plan to the first, but dealing with contributions since 1896. It is remarkable that so much good work has been done in this period, which includes the War years. The book will be a most valuable aid to geometrical research. H. T. H. P.

*Storia delle matematiche*. Per Prof. Gino Loria. Vol. 2. *I secoli XVI e XVII*. Pp. 595. (Torino: Società Tipografico-Editrice Nazionale, 1931.) 25 lire.

THIS admirable work continues the history of mathematics into the sixteenth and seventeenth centuries. This period, which includes such great names as Tartaglia, Napier, Descartes, Galileo, Fermat, Leibniz, and Newton, to cite only a few, presents to the historian a difficult task of discrimination. Prof. Loria has approached the subject on the lines laid down by Montucla: "L'histoire d'une science n'est pas celle de tous les auteurs qui en ont écrit, mais seulement de ceux qui ont contribué par leur travaux à en reculer les bornes." Nevertheless, he has chosen the matter with such care that very little which is of historical importance seems to have escaped the net. Each chapter is accompanied by a very full bibliography which permits a more detailed study of any particular point on which further information may be required.

## Metallurgical Researches of Michael Faraday.

PRIOR to 1819, when Faraday published a paper on the composition of Indian Wootz steel, his contributions to knowledge had been represented by comparatively short communications, with no very obvious connexion. His first research of any magnitude was, therefore, the one on the alloys of steel with other metals, on which he was engaged for the next five years. This work, carried out in collaboration with a Mr. James Stodart, a manufacturer of cutlery and surgical instruments, led to the publication of two further papers in 1820 and 1822. Of these, the former is an account of small scale experiments made in the laboratory of the Royal Institution, and the latter, on ingots, 10 lb.-20 lb. in weight, melted in Sheffield. The cause of this interest in steel cannot now with certainty be determined, but Faraday's association with Stodart, and a decision of the Board of Management of the Royal Institution of 1812 that it was desirable that experiments should be undertaken on the alloys of metals, may both have played important parts.

That Stodart's influence was probably considerable is indicated both by the subject of Faraday's first metallurgical contribution and by the fact that after Stodart's death, in 1823, no further paper on this subject appeared. Faraday's diary contains but three further references to steel, the last of which is dated June 28, 1824. That Stodart was much impressed by the Wootz steel is shown by his trade card, preserved in the British Museum, which reads: "J. Stodart, at 401, Strand, London, Surgeons Instruments, Razors and other Cutlery made from Wootz, a steel from India, preferred by Mr. Stodart to the best steel in Europe after years of comparative trial". The desire to imitate this steel for surgical and other cutlery was clearly one of the main objects of Faraday's research, the other to prepare an alloy suitable for mirrors which would not corrode.

Before discussing the results to which this work led, it is not without interest to attempt to discover why it came to such a sudden and untimely end. For this, Stodart's death must in some measure be held responsible; for after giving Faraday every credit for his (in all probability very large) share in the work, the practical experience and keen interest of his collaborator must have exercised a considerable influence. This, probably, with a growing enthusiasm for other lines of research, and a feeling of disappointment with the results obtained from his work on steel, evidently caused his interest to wane. The opinions of his scientific contemporaries are well indicated by the following extract from the obituary notice to Faraday in the *Proceedings of the Royal Society*: "The results of the paper on steel by Stodart and Faraday to the Royal Society in 1822, were of no practical value, and this, one of his first and most laborious investigations, is strikingly distinguished from all his other works by ending in nothing".

That the research was laborious is well shown by one of Faraday's own letters, in which he says:

"Pray, pity us that, after two years' experiments, we have got no further; but I am sure, if you knew the labour of the experiments, you would applaud us for our perseverance at least".

What, then, were the fruits, if any, of this five years of continued research? It is to Faraday's credit that, for the first time, a series of steels were examined with sixteen different metallic additions and of varying concentrations. Secondly, he determined, in all probability as accurately as has been done even to the present day, the solid solubility, which he gives as 0.2 per cent, of silver in steel. This was, the writer believes, the first time that such a determination had ever been made. He further showed that both platinum and rhodium dissolve in steel in all proportions; for the former metal this was confirmed in 1907, whilst for the latter it still remains the only research ever carried out.

Faraday prepared the first of the 'stainless steels'. That the alloy contained 50 per cent of platinum, and hence found no useful application, does not detract from a scientific discovery of first-rate importance. Next, by treatment of a steel with acid, he prepared from it a "soft, grey, plumbaginous powder" which, he says, "appears to be a carburet of iron". Priestley, it is believed, had done this at an even earlier date, but Faraday's rediscovery of iron carbide in steel appears to have been entirely independent. By heating a polished surface of his chromium steel, Faraday developed its structure; the very first use of the process now known as 'heat-tinting'. In considering the effect of titanium on steel, he came to the conclusion, which is most generally accepted to-day, that this element does exert a distinctly beneficial effect, but that it finds no permanent place in the steel to which it is added. Considering his experiments on the rusting of the special steels, he points out that nickel reduces the tendency to corrode, and that, other things being equal, a high carbon steel rusts more rapidly than does one of lower carbon content. Finally, he observes that his rhodium steel is more resistant to softening by tempering than a plain carbon alloy is, a conclusion which, if followed up, might well have led to the production of steels of the high-speed type long before they were actually devised.

This, then, is part of the fruit of a research which "ended in nothing". If, however, both Faraday and his scientific contemporaries failed to realise the importance of the results which had been obtained, and to build upon the foundations which he had laid, there are clear indications that a certain section of the producers of steel were greatly impressed. The one steel which Faraday picks out from all he produced was that containing a small percentage of silver. In his own words, "its alloy with steel is the most valuable of those which we have made. To enumerate its applications would be to name almost every edge-tool. It is also probable that it will prove valuable for making dies,

especially with the best Indian steel." In the later paper, dealing with the large scale experiments, he again says that it "was harder than the best cast steel or even than the Indian Wootz, with no disposition whatever to crack either under the hammer or in hardening—its application will probably be extended not only to the manufacture of cutlery, but also to various descriptions of tools; the trifling addition of price cannot operate against its very general introduction. The silver alloy may

result of Faraday's work, and provide some indication of the esteem in which it was held by the actual steel-makers.

What has become of the ingots cast in Sheffield will in all probability never be known, but of the steels prepared in the Royal Institution we have now a most interesting and detailed knowledge. A wooden box labelled 'Faraday' and 'Steel and Alloys', the former probably, and the latter almost certainly, in his own writing, has recently

FIG. 1.—The seventy-nine steel specimens taken from Faraday's box. Reproduced by courtesy of the Royal Society from *Phil. Trans.*, A, vol. 230.

be advantageously used for almost every purpose for which good steel is required."

Even to-day there is on the market the so-called 'silver-steel', which, in general, is quite free from that metal, the name referring merely to a high-class, high-carbon crucible alloy. The writer well remembers a visit to a crucible steel works in Sheffield some twenty-five years ago, and seeing the head-melter, with much ostentation, dropping a sixpenny piece into the 'pot' containing some sixty pounds of liquid steel, which addition he was assured would confer on the metal superlative qualities. There can be very little doubt that both the name and the practice are the direct

come to light. This contained seventy-nine specimens, which were handed over to Sir Robert Hadfield for investigation. An account by him of an examination of these, which historically is of the very first importance, has now been published (*Phil. Trans.*, A, vol. 230, p. 221, and *British Assoc.*, Sept. 24, 1931). The scrupulous care taken of this unique material is indicated by the fact that although about 430 separate chemical estimations have been made, with 210 other determinations of structure, hardness, specific gravity, resistance to corrosion, magnetic and electrical characteristics, etc., more than 6½ lb. of the steel still remains, from an original weight of less than 8 lb., representing more than

seventy-five per cent of the total. The samples themselves are shown in Fig. 1.

Broadly, the samples fall into the following categories. In group *A* are three 'buttons', evidently the original melts as they solidified from the furnace. These, like the samples in group *B*, weigh at most 4.5 oz., the latter section, however, consisting of roughly hammered 'blooms'. In group *C* these small 'blooms' have been further hammered into bars. One such bar, however, is far more regularly fashioned, and from its analysis Sir Robert Hadfield draws the perfectly logical deduction that it may well have formed a portion of the steel which Faraday used as the raw material for some of his melts. The other type of basis metal appears to have been an English wrought iron of low carbon and considerable purity for a material of such origin. That a low carbon base must have been employed for some of the melts is shown by the fact that among the samples which have already been analysed is one which contains only 0.07 per cent of carbon and 2.25 per cent of platinum. Some idea of the quality of this achievement, bearing in mind the primitive apparatus available, will, perhaps, be better appreciated if it is pointed out that when, some seventy years later in 1894, Arnold carried out his classical research on "The Influence of Elements on Iron"

with an equipment vastly more complete and satisfactory than anything which Faraday had at his disposal, in three cases only out of ten was a smaller amount of carbon present in the alloy than in this remarkable material which Faraday turned out in his simple 'blast-furnace'.

The importance of the production of an untarnishable steel for mirrors in this research is shown by a whole group of other samples with one or more highly polished surfaces. Among the samples from the Royal Institution, the high platinum-metal alloys were not represented. The steel noted by Faraday which, as a result of the large proportion of platinum it contained, did not corrode, was not, therefore, examined. Quite recently, however, a further series of samples, the property of Mr. A. Evelyn Barnard, has been discovered by Sir Henry Lyons. These also have been placed at Sir Robert Hadfield's disposal for examination, and in a preliminary note in the paper read before Section G (Engineering) of the British Association, high platinum, rhodium, and palladium steels, of such a composition that they can only represent Faraday's alloys, have been found. To all interested in metallurgy, in Faraday himself, and in the history of scientific discovery, the investigation of these alloys will be a matter of the greatest interest. F. C. T.

### Xeromorphic Adaptations of Plants.

THE leaves of plants which are found growing in dry situations often show certain structural characteristics in common—thick-walled tissues, thick cuticles, stomata sunken below the surface, etc. These structural features seemed likely to cut down the loss of water from the leaf, and therefore, with little experimental investigation, they have been classed as adaptational mechanisms against water loss and spoken of as 'xeromorphic'. Of recent years the experiments have been carried out which should properly have preceded the adoption of any such interpretation of these characteristic structures.

The result has been considerable misgiving as to the soundness of a view that had long held its place in the elementary textbooks and a great recrudescence of interest in the problem, as is well illustrated by the symposium on xeromorphy at the International Botanical Congress at Cambridge in 1930. Papers by Maximow, Huber, Schratz, and Thoday, which were read at this symposium, have now appeared,<sup>1</sup> whilst an interesting résumé of some aspects of the subject has been published by E. G. Pringsheim.<sup>2</sup>

It is by no means easy to obtain good comparative figures of evaporation rates from different leafy shoots. It is dangerous to assume that twigs removed from the plant will give values indicative of the behaviour of the same shoots upon the tree, and Schratz points out also that the comparative rates of evaporation determined for different severed shoots will vary with the duration of time employed in making the observation.

Results with the shoots still growing upon the

plant would therefore appear more valuable, but the difficulty now lies in finding a practicable method for determining the comparable rates of water loss, whilst at the same time it is clear that the structural features of the shoot tissues immediately in question, are only one amongst many variables determining the evaporation from the plant. Seybold's method<sup>3</sup> of treating the evaporating surface as a wet bulb hygrometer seems a step in the right direction and is applicable with the growing plant, but, as Maximow points out, the real temperature of the transpiring surface is still in doubt.

In view of the experimental difficulties, it is not surprising that there is still considerable difference of opinion as to the significance of xeromorphic structures, but a certain general measure of agreement seems to emerge when these recent papers are examined. Thus it seems to be generally agreed that xeromorphic leaves have about the same proportion of stomata to epidermal cells as less xeromorphic leaves of the same species. As the cells of the xeromorphic leaf are usually smaller, this means that the xeromorphic leaf has a larger number of stomata per unit surface, so that it is not surprising to find that, when the stomata are open and the leaves freely supplied with water, xeromorphic leaves lose water more rapidly than less xeromorphic leaves of the same plant. The point is made very clearly by Huber in his comparison of 'sun' and 'shade' leaves, where the sun leaves, borne near the top of the leafy crown of the tree, are xeromorphic as compared with the shade leaves of the lower branches. Such

sun leaves under equal experimental conditions, upon detached shoots given a liberal water supply, evaporate relatively more water than the shade leaves

On the other hand, under conditions of water deficit, such as will occur more frequently to 'sun' leaves or plants of dry habitats, whilst the adjustment of stomatal aperture is usually more sluggish in such leaves—so that the shade leaves and the plants of normal, mesophytic habitats restrict their water loss more rapidly with diminishing water supply—when once the stomata are closed the loss of water from the xeromorphic leaves is much slower and they do not dry out and wilt like the mesomorphic leaves. Maximow emphasises the fact that they recover more readily after such exposure to drought, and regards this as perhaps the outstanding factor in their resistance to drought,<sup>3</sup> but most contributors to the recent discussions on this subject could agree with his recasting of Schimper's original definition to read that "xerophytes are plants of dry habitats which are able to decrease the transpiration rate to a minimum when under conditions of water deficiency"

From the new point of view, many of the structural features of these xerophytes may come to be regarded rather as natural consequences of growth in a dry habitat than as direct biological adaptations to minimise water loss. Thicker cuticles and thicker walls may be natural results of growth under conditions which repeatedly favour excessive water loss—and therefore processes of deposition

from solution and of chemical condensation—during the growing period

Pringsheim's paper, as also an interesting footnote to Thoday's paper, suggests that a re-examination of 'water-storage' tissues will also become necessary as the water relations of the cell are better understood. The work of Ursprung and Blum has created the impression that volume changes of the cell are mainly governed by the elastic properties of the cellulose wall, but most of the increase in cell volume during growth is irreversible, and Oppenheimer has recently criticised very effectively<sup>4</sup> the experimental basis of this work. He has shown that reversible alterations in volume of about twenty per cent may be seen in thin-walled cells but not in typical thick-walled cells. On the other hand, as Pringsheim points out, the wall may follow alterations in volume of the cell, due directly or indirectly to water loss upon evaporation, although not a stretched elastic membrane. Upon the possibility of such volume changes, in which cell size and shape and tissue configuration will play an important rôle, will largely depend the availability of the water in the cell to supply the needs of other tissues. Thus a large-celled, thick-walled parenchyma may lose water to a thin-walled small-celled meristematic tissue in which volume changes are less easily induced as the result of water loss

### Problems of Filterable Viruses.

THE frequency in recent years of viruses and virus diseases as subjects for discussion at international congresses testifies alike to the wide interest manifested in the biological problems that await solution and to the far-reaching economic importance of this type of infection in the animal and plant worlds. In *NATURE* of Oct. 10 appeared the main part of Dr. H. H. Dale's presidential address to Section I of the British Association. This address dealt strictly with the biological nature of viruses, an aspect of the general virus problem which, in spite of intensive research in many countries, is likely to offer for some considerable time yet abundant scope for speculation. Dr. Dale's careful analysis of the available information led him, on the whole, to favour as the best working hypothesis one which postulates that the viruses are independent living entities and not of the nature of intrinsic cell ferments or catalysts.

The address was followed by a well-maintained discussion in which a number of active workers in the virus field took part. Dr. Ravers (Rockefeller Institute) emphasised the intimate relation that appeared to exist between the viruses and their host cells as evidenced by the occurrence in certain host cells of inclusion bodies one type of which, notably the Bollinger body of fowlpox, undoubtedly contains virus, and by the fact that positive results in the course of attempts to cultivate viruses *in vitro* had been obtained only when living cells were

present. He and his co-workers had failed to demonstrate growth of vaccinia virus in purely artificial media free of tissue cells. It was fairly obvious from the blackboard schemata which Dr. Ravers had prepared in order to illustrate certain possible ways in which viruses could be explained on an intrinsic or semi-intrinsic basis, that he treated perhaps with unmerited seriousness the opinions of certain pathologists who have recently expressed themselves in a similar strain. Subsequent speakers, from their experience in the plant and animal virus fields, were overwhelmingly of opinion that, for the time being at any rate, the hypothesis that viruses are extrinsic living entities is good enough to work on, seeing that no fact yet established in regard to the features of viruses in general and their reactions both in the body and in the test-tube is incompatible with such hypothesis.

This view was stressed particularly by Dr. Henderson Smith (Rothamsted) from the plant virus side, while in the animal virus field Dr. Bedson (London Hospital) and Dr. C. H. Andrewes (National Institute) emphasised the entire incompatibility of an intrinsic origin with the known facts which have been ascertained with regard to the antigenic individuality of viruses. In no essential particular is their serological behaviour—whether in the body or in the test-tube—different from that of the visible bacteria, and the acceptance of an intrinsic origin would involve assumptions as to

antigen-antibody relationships which run counter to all our accumulated knowledge of serology. As pointed out by Dr W E Gye (National Institute), however, there appeared to be some experimental evidence derived from his work on transmissible fowl tumours that the induction of a tumour by means of a cell-free filtrate is brought about by the co-operative action of two elements, one arising intrinsically and the other (most probably the virus) extrinsically.

Dr G H Eagles (Lister Institute), who has recently reported success in the cultivation of the virus of vaccinia on artificial media free from cells (centrifuged kidney extracts), pointed out that if criticism was directed to these experiments on the ground that the centrifugalisation was incomplete, the very notable multiplication of the virus would have to be accounted for by the presence of such a minimal amount of intact cell substance as could scarcely play any decisive rôle in facilitating growth.

Important evidence was given bearing on the well-founded assumption that, below the smallest visible bacteria, another range of living entities begins, going down, so far as we can judge, to degrees of smallness which, at the moment perhaps, it is difficult to conceive as capable of association with an independent life process.

Prof Ledingham (Lister Institute) discussed the evidence in support of the belief that the large inclusion bodies met with in the epithelial cells in fowlpox are made up of elementary bodies (Borrel bodies) about  $0.2 \mu$  diam, and that these latter are the actual infective agents. He stated that he had recently been able, by a special process of extrac-

tion, to secure pure suspensions of the elementary bodies (Paschen bodies and Borrel bodies) present in the lesions of vaccinia and fowlpox respectively. These suspensions were found to be agglutinated by the sera of animals (rabbits and fowls) in the course of infection with, and after recovery from, vaccinia and fowlpox. This new evidence supported the view that the elementary bodies were of etiological importance.

Mr J E Barnard and Dr W J Elford (National Institute) discussed their recent work on the microscopy of the elementary bodies present in the lesions of ectromelia, the recently discovered disease of mice which, like fowlpox, is associated with the presence of characteristic large inclusion bodies in the epithelial cells of the infected mouse skin. They showed that, as in fowlpox, the inclusion body in this disease is similarly made up of elementary bodies which are also to be found in great numbers in infected organs such as the liver.

The diameter of the elementary body (about  $0.15 \mu$ ), as determined by microscopical methods, agreed closely with that determined from differential filtration methods in which collodion membranes of varying porosity were used. The diameter of the foot and mouth virus particle, on the other hand, when determined by similar filtration methods, in conjunction with biological tests of the filtrates, appeared to be of the order of  $25-30 \mu$ , and thus only some three times larger than the diameter of a hæmoglobin molecule.

The discussion as a whole brought to a focus a number of the more important lines on which virus research is at present concentrating, and the outlook for the future was distinctly optimistic.

### Obituary.

DR GUSTAVE LE BON.

THE death of Dr Gustave Le Bon, at the age of ninety-two years, removes one of the most brilliant and versatile of French savants. Ethnology, sociology, psychology, history, philosophy, and experimental science occupied his attention in turn, and often simultaneously.

Le Bon began his professional career as medical officer of a military ambulance in 1870. His early publications refer to experimental work in physics and chemistry, including a study of the alkaloids of tobacco smoke (1880). An adventurous nature led Le Bon to take part in many explorations and scientific missions, which supplied him with material for several ethnographical and sociological studies, such as "La Civilisation des Arabes" (1884), "Les Civilisations de l'Inde" (1887), "Les Premières Civilisations de l'Orient" (1889). Le Bon came to the conclusion that races differ from one another in the proportion of higher types of individuals that they contain, and that the difference between the sexes becomes greater in the more advanced civilisations.

The writings by which Le Bon was best known are his psychological works. The "Psychology of Crowds", "Psychology of Education", "Psycho-

logy of Socialism", etc., have been very widely read, and have exerted a wide influence on contemporary thought. Le Bon was also known for his pioneer work in connexion with the relation between matter and energy. In 1897, in a communication to the Paris Academy of Sciences, Le Bon declared that all bodies under the influence of light emit radiation capable of rendering the air a conductor of electricity. He pointed out that this radiation was probably related to the cathode rays and to the newly discovered Becquerel radiation from uranium. His opinion that "matter is only a stable form of energy" was considered at the time highly unorthodox and met with vehement opposition. These speculations were brought together in his "L'Évolution de la Matière" (1905) and "L'Évolution des Forces" (1907), the latter of which was translated into English.

Le Bon counted among his friends some of the most distinguished French savants, including Henri Poincaré, Painlevé, and Ribot, and had perhaps more admirers outside France than in his own country. He was born in 1841 at Nogent-le-Rotrou, and died at Marnes-la-Coquette of bronchopneumonia, after a short illness. As director of the Library of the Philosophy of Science, he remained active in scientific matters until the end.

## News and Views.

## New Year Honours.

THE New Year Honours list contains the names of the following scientific workers and others associated with scientific work —*KCMG* · Sir James Kingston Fowler, member of the Colonial Advisory Medical Committee *KBE* Dr F N K Menzies, chief medical officer of the London County Council *DBE* Miss Margaret Tuke, formerly principal of Bedford College for Women, Miss Edith Mary Brown, principal of the Women's Hospital and Christian Medical College, Ludhiana, Punjab *Knights* Mr George Buckston Browne, who purchased the house at Downe, Kent, where Charles Darwin lived, restored and endowed it, and gave it to the British Association in custody for the nation, Dr H H Dale, director-in-chief of the National Institute for Medical Research, Hampstead, Prof P Geddes, emeritus professor of botany in the University of St Andrews and formerly professor of sociology and civics, University of Bombay, Dr H S Wellcome, founder of the Wellcome Research Institution and of the Wellcome Tropical Research Laboratories, Khartoum *CB* Mr F W C Dean, formerly superintendent of the Royal Gun and Carriage Factories, Royal Ordnance Factories *CMG* Dr E. J. Butler, director of the Imperial Mycological Institute *CIE* Lieut-Col J Morrison, director of the King Edward VII Pasteur Institute and Medical Research Institute, Shillong, Assam, Dr N. L. Sheldon, chief inspector of explosives in India. *CBE* Dr Harriette Chick, for services to the Medical Research Council in connexion with research on vitamins and the science of nutrition, Maj T J Hallman, inspector-general of health services, Ministry of the Interior, Iraq; Mr H. H. Humphries, city engineer and surveyor, Birmingham, Mr V A Lowinger, surveyor-general in the Straits Settlements and Federated Malay States, Mr G K Menzies, secretary to the Royal Society of Arts, Mr. R J Mitchell, director and chief designer, Supermarine Aviation Works (Vickers), Limited, for services in connexion with the Schneider Trophy contest, Dr H Moore, director of metallurgical research, War Office, Mr H E Stilgoe, chief engineer Metropolitan Water Board, Mr J M Thomson, secretary for native affairs, Northern Rhodesia, Mr C Weatherill, assistant secretary and acting deputy secretary, Department of Agriculture for Scotland *OBE* Capt B S Cohen, staff engineer, Research Section, General Post Office, Mr A Harker, for services to the Committee for Research in the Dependencies of the Falkland Islands (Discovery Committee), Mr F. A. Innes, medical officer of health, Gambia, Mr R Withycombe, director of the Electricity Department, Zanzibar. *MBE* Mr W N Booth, assistant mechanical engineer, Royal Ordnance Factories, Woolwich, Mr C J Colvin, assistant engineer, Irrigation, Ministry of Economics and Communications, Iraq, Mr W W D Dale, engineering assistant to the Director of Dockyards, Admiralty,

Mr J E Lesslar, formerly senior deputy pathologist, Institute for Medical Research, Federated Malay States

## Dr D H. Scott

DR D H SCOTT has recently received a diploma of congratulation from the Bavarian Academy of Science, through its president, Prof K Ritter von Goebel, on the jubilee of his degree of Ph D of the University of Wurzburg. The degree was conferred on Dr Scott on July 20, 1881. Dr Scott is known chiefly for his work in palaeobotany and in this field he has earned a world-wide reputation. He was elected a fellow of the Royal Society in 1894, and was awarded a Royal Medal in 1906 for his investigation and discoveries in connexion with the structure and relationships of fossil plants, and the Darwin Medal in 1926 for his work on the Pteridosperms. Prof von Goebel, through whom the congratulatory diploma was sent, was elected a foreign member of the Royal Society in 1926. He is well known for his studies in plant organography, and is an authority on the Bryophyta. This recent further recognition of one of the leading British botanists by his German colleagues is a graceful tribute which will be widely appreciated.

## Synthesis of Vitamin D.

THE announcement appeared in *NATURE* of Oct 31, 1931, p 758, of the preparation of 'calciferol', a crystalline compound of the highest known vitamin D activity, by a team of workers at the National Institute for Medical Research, under the leadership of Dr Bourdillon. Calciferol is probably the pure vitamin, although this is not quite certain. Members of this group of compounds, in mixtures of varying composition, frequently form crystals which cannot be separated into their components by simple recrystallisation but only by the formation of derivatives. Calciferol is formed from ergosterol by the action of ultra-violet rays, and up to the present no other method of conversion of ergosterol into vitamin D has been successfully used. It is now reported in the *Times* of Jan 1 that C E Bills and F G McDonald, of Evansville, Indiana, U.S.A., have claimed the first chemical synthesis of this vitamin, in a paper at the recent meeting of the American Association for the Advancement of Science. They treated ergosterol with methyl alcohol, ether, and ethylacetate under low temperature, with a rigid exclusion of oxygen, and obtained the vitamin, but in less pure form than by the irradiation of ergosterol.

SYNTHESIS of vitamin D without the use of ultra-violet rays is of very great interest. The fact that the product is of only low activity indicates that it is impure. This work suggests a number of further problems for elucidation. Will the vitamin so prepared, when isolated in pure form, be the same as 'calciferol'? *A priori*, this might be expected

Again, will the method be simpler to use than that involving the use of ultra-violet rays, and will the conversion be more quantitative as the method is improved? It will also be of interest to observe whether the methods used by Bourdillon and his collaborators in England and by Windaus at Göttingen in the separation of the vitamin from its accompanying impurities in irradiated ergosterol are applicable to 'chemically-treated' ergosterol. Further details of Bills and McDonald's process will be awaited with interest.

#### Power Stations and Air Pollution.

DURING the past two years, public attention in Great Britain has been focused on the question of air pollution due to the operation of super-power electric stations. In his recent presidential address to the Junior Institution of Engineers, Dr S. L. Pearce, engineer-in-chief of the London Power Company, discusses this problem and others of great importance at the present time owing to the practice of concentrating more and more power in single generating stations. Efficient measures are available for preventing the pollution of the atmosphere by the smoke and ash from chimney-stacks when stoker-fired boilers are used, but when pulverised fuel is adopted the problem becomes more difficult, owing to the fineness of the dust content of the ash. The recent controversy about the new Battersea power station had reference to the much more difficult problem of arresting the possible damage to buildings and vegetation, and the alleged danger to life, due to the sulphur oxides contained in the products of combustion issuing from the chimneys.

Most of those who discussed this problem attributed the pollution of the atmosphere mainly to the power stations. That some of it is due to this cause every one admits, but the great bulk is due to the many industrial power plants and the hundreds of thousands of domestic chimneys. Effective measures are now available for eliminating smoke and the ash and dust content of flue gases. Cyclone plants, spray and film washers, and electrofilters all find a place in modern power stations. In conjunction with these, however, it is necessary to erect chimneys at least 300 ft in height. During the last three years, by the collaboration of engineers and chemists, much research work has been carried out by the London Power Company, experimental plants have been erected, and the results obtained have proved conclusively that the emission of sulphur fumes can be reduced to a negligible quantity.

#### Akhenaton's Mummy.

THE consternation aroused a few weeks ago by the reported discovery that the mummy of Akhenaton exhibited in the Cairo Museum was not that of the famous monarch, and the suggestion that a substitution had taken place, has now been allayed in some degree by the announcement that it is the identity of the mummy that is in question. Dr D. E. Derry and Mr. Rex Engelbach, curator of the Egyptian Museum, in a joint lecture at Cairo, as reported in the

*Times* of Jan. 2, have now put forward the view that the mummy hitherto regarded as that of Akhenaton is really that of Smenkara, a son-in-law of Akhenaton, who used the royal name in his cartouche, hence the confusion. This mummy has presented some elements of doubt from the time of its discovery. It was found in 1907 in the Valley of the Kings, in a tomb supposed to be that of Queen Tiye. When it was examined by Prof. Elliot Smith, the condition of the bones was such as to suggest that they belonged to a young man who, at the time of his death, was not more than twenty-five years of age. As this seemed difficult to reconcile with the known facts that Akhenaton had reigned for seventeen years and had six daughters, Prof. Elliot Smith suggested that the king might have suffered from a rare affection which would have delayed the consolidation of the bones perhaps for as much as ten years beyond the normal ("The Royal Mummies", pp. 52-53). Dr. Derry, as a result of experience in the examination of the modern Egyptian youth, now thinks that the mummy may be that of an individual of even less than twenty-five years of age, in view of the early age at which maturity is attained in Egypt. Further, the bulbous head, well known in the representations of Akhenaton and taken by Prof. Elliot Smith in the actual skull to be due to a slight degree of hydrocephalus, is regarded by Dr. Derry as a characteristic of Egyptian royalties.

#### Exhibition by the Royal Meteorological Society

AN exhibition is being arranged by the Royal Meteorological Society, to be held in the Geophysical Gallery of the Science Museum, South Kensington, by permission of the director, Sir Henry Lyons. The exhibits will include modern types of observing instruments approved by the Meteorological Office, such as the latest type of thermometer screen with steel stand, equipped with sheath thermometers, the sunshine recorder Mark II, with adjustments for level and azimuth, a new form of mountain rain-gauge which has been named the 'octapent' mountain rain-gauge, and a stream-lined wind-vane which embodies a number of new features—these are being lent by the director. Several stands of instruments of special interest will be shown by some of the leading British makers, among which will be a model anemometer, a new form of automatic pollution gauge, and examples of 'distant-reading' thermometers. A number of historic instruments will be shown, and another exhibit will illustrate the development of lightning conductors.

OTHER features of the exhibition will be a magnificent collection of cloud photographs, including a series arranged by Sir Gilbert Walker, showing recent work on the artificial production of cloud forms. There will be a small exhibit illustrating the teaching of weather study in schools. The exhibition will be opened at 5 P.M., on Jan. 11, when a short inaugural address will be given by Sir Napier Shaw in the lecture theatre. The exhibition will remain open for one month, during which public lectures will be given on Thursdays at 4.30 P.M. The programme as provisionally arranged is as follows: Jan. 14—Mr. D.

Brunt, on "Meteorology in History", Jan 21—Dr G C Simpson, on "Weather Forecasting", Jan 28—Capt C J P Cave, on "Clouds", and Feb 4—Sir Henry Lyons, on "Historic Meteorological Instruments"

#### Blind Reading Print by Sound

ACCORDING to a report in the *Times* of Jan 1, two French inventors, MM Thomas and Conland, have devised an apparatus by which ordinary print can be made legible for the blind. The apparatus is called the photoelectrograph. A ray of light is made to pass over the printed page, and as each letter is illuminated the corresponding letter is presented in relief and in magnified form in another part of the machine, where the blind reader identifies it by touch. Not only ordinary print, but also Braille can be read with the machine, in the latter case it has the advantage that the Braille characters can be printed with ink on a smooth page and need be no larger than ordinary type, thus reducing Braille types to a convenient size and making them cheaper and easier to produce than hitherto. Any reduction in the size of the present Braille publications in embossed type must be a boon, but institutions for the blind in Great Britain will probably continue to use an instrument which involves no special printing, and—like Dr Fournier d'Albe's 'optophone' or Prof F C Browne's 'phon-opticon'—directly converts ordinary type into sound signals. Moreover, experience has shown that ordinary type, even after enlargement, is unsuitable for reading by touch with any speed.

#### Scientific Research and the Electrical Industry

WE learn from *A E G Progress* for October that owing to the present trade depression, the German electrical industry is being compelled to exercise the most rigid economy. On the other hand, it is doing its utmost to explore the possibilities of new sources of revenue. To achieve this, it is relying on scientific research and on utilising the results obtained in industry and agriculture. It is recognised that many of the benefits conferred on the civilised world during the last two generations have been due to the close co-operation between the research worker and the engineer. The Research Institute of the A E G, which commenced work as a private institute several years ago, has now opened its doors to a wider public and to the Press. Prof Ramsauer is the head of the Institute and has forty scientific workers under him, the problems investigated covering a wide field in physics, chemistry, and engineering. The field of purely scientific research is the field in which the Institute is least fettered, as the question of technical application is of secondary importance. In fact, technical considerations may be a drawback, as a pre-determined purpose cramps scientific research and may even lead it astray. Only when the investigations have been carried to a conclusion, uninfluenced by preconceived ideas, is the possible use of the technical applications of the results considered. In this way the nature of the electron was investigated in the physical laboratory and the conclusion arrived at that its behaviour is similar to that of a wave. It

is stated that the use of electron waves for surface structure analysis represents a valued and important application of the knowledge thus obtained.

#### Soap Plants

ETYMOLOGY, pharmaceutical lore, and wide knowledge of ancient herbals and modern systematic botany are combined in the fascinating series of articles contributed by Mr Hilderic Friend to the *Gardeners' Chronicle* under the general title of "Horticulture in relation to Commerce". The article in the issue for Nov 28 points out how varied are the plants and parts of plants that have been used by native races as soap materials. As a result, the identification of a plant simply named a soap plant or soapwort is not an easy matter. One tropical family, the Sapindaceæ, represented commonly in Great Britain by the horse-chestnut, contains a number of soap plants, including the soap-tree of China, *Sapindus chinensis*, the fruit of another species is used in India under the name of soap nut, whilst Humboldt describes the natives on the river Carriaco washing their linen with the fruit of the parapara (*Sapindus Saponaria*). In California is found a large bulb, *Chlorogalum pomeridianum*, of which the mucilage provides a lather, whilst the root of *Gypsophila Struthium*, a native of Spain, lathers in water. In fact, decoctions, roots, barks, fruits, and seeds have all been utilised, whilst the modern soap industry probably had its origin in the value, very early discovered, of certain plant ashes as cleansing agents. Thus, Pliny states that soap was first prepared by boiling goat's fat with ashes from the beech tree.

#### Strength of Burmese Timbers

A PAPER comparing timbers of Burma with those of Europe and America, by Mr C W Scott, of the Indian Forest Service, was recently presented to the Association of Engineers in Burma (Paper No 3, July 23, 1931, Session 1931). Timber testing is now an economic art practised in many countries either anxious to place new untried timbers on the markets or to procure cheaper ones to replace more expensive types. Most of the important timbers of Burma have now been tested for strength on standard scientific lines at the Forest Research Institute, Dehra Dun, India. The data obtained there are readily comparable with those recorded by similar apparatus and procedure in the United States, Canada, and Great Britain. Timber testing has indeed become a highly organised branch of science in the last twenty years. It is conducted under the supervision of trained engineers well acquainted with engineering practice and requirements in metal and other materials as well as in wood. In France and Germany a certain amount of special timber testing has been done in connexion with aircraft, but apparently no standard procedure for general timber testing has been evolved. The standard methods used at Dehra Dun are being followed also in Australia, New Zealand, South Africa, the Malay States, the Philippines, and Java. Mr Scott's paper is of value, since the data of comparison have been collected from the laboratories of Dehra Dun (India), Madison (U S), Princes Risborough

(England), and the Forest Products Laboratories of Canada. From the point of view of Burma, it places that country in a position to answer inquiries on the subject of strengths, etc., of her more important timbers, information on the subject being obtainable from the Forest Economist, Rangoon.

#### American Museum of Natural History

THE standing and the progress of the American Museum of Natural History illustrate what can be attained by effort over a relatively limited field so long as public interest approves and lends its support. On the common ground of the great public educational purposes served by the museum, the City and State of New York have combined in granting appropriations for building alone of 16,000,000 dollars, and the increasing extent of the services rendered may be judged from the jump which is foreshadowed in annual expenditure, from the "inadequate sum" of 15,000,000 dollars in January 1931 to an amount of 22,500,000 dollars in 1933, when the building programme will be completed, and the exhibition halls, laboratories, and lecture halls will be in full operation (Sixty-second Annual Report of the Trustees for the Year 1930). A new feature of the museum's educational programme is the development of the training of teachers, for whom three special courses have been instituted. But the school services also increase by leaps and bounds, so that the 23,000,000 contacts with school children in 1930 almost double those of the year before. The lantern slides loaned to public schools well exceeded a million, and it is interesting to find that the growth of the film service shows that for class purposes the narrow width film (16 mm) is more appreciated as an aid in teaching than the standard (35 mm) film, the real place of which is the assembly hall.

#### National Museum of Canada

THE National Museum of Canada, the Annual Report of which for 1929 has just been published, attains a happy balance in its combination of field and indoor work. During the summer months the members of the staff are engaged in field work broadly distributed throughout Canada, a tradition doubtless derived from the Museum's close connexion with the Geological Survey. The result is of value scientifically and educationally. Ethnological expeditions in many areas, the investigation of the mammals of British Columbia and of the plants of Wood Buffalo Park, add material to the collections and valuable experience to the collectors, who take the opportunity of delivering popular lectures in the districts they visit. In the Museum itself great stress is laid upon the need for making a reasonable contribution to the interests of the community, and the variety of the titles in the list of the two popular lecture courses, delivered during the winter in the auditorium, indicate one way in which that contribution is successfully made. Nearly 9000 children attended the Saturday morning lectures and 3323 adults those on Wednesday evenings.

#### Literature of Nutrition.

THE scientific investigation of nutritional problems has attracted so many workers to this field that it is

difficult for anyone to keep in touch with advances made in directions other than those in which he is immediately engaged. We therefore welcome the appearance of the first two parts of vol. 1 of *Nutrition Abstracts and Reviews*. This new journal is issued under the auspices of the Imperial Agricultural Bureaux Council, the Medical Research Council, and the Reid Library of the Rowett Institute, Aberdeen. The editors are Dr J B Orr, Prof J J R Macleod, and Dr Harriette Chick. The first number, a double one, contains 351 pages and 1334 abstracts. Reviews are contributed by Sir F Gowland Hopkins on nutrition and human welfare, Prof E P Cathcart on some of the difficulties in the quantitative assessment of human diets, and Dr J B Orr on the qualitative aspects of nutrition, with special reference to farm animals. The journal will appear quarterly. Abstracts will be made from some 450 periodicals, and the reviews will be of two types, those of a general nature, stating a point of view, as in the present number, and others dealing exhaustively with the present state of knowledge of different aspects of the subject, giving a bibliography of the literature. A hearty welcome may be extended to the new journal, which will be invaluable to workers in this science and of great use as a work of reference.

#### British Salmon Fisheries in 1930

THE Ministry of Agriculture and Fisheries Report on the Salmon and Freshwater Fisheries for the year 1930 brings to our notice that that year was characterised throughout Great Britain by the marked shortage of salmon from our rivers. Furthermore, this had followed on from a shortage that was already apparent in 1929. In both years it was the four-year-old fish which failed to come up to number, which indicates that for some reason the smolt crop of two successive seasons, in 1927 and 1928, has not returned from the sea. All available evidence goes to show no reason that would cause the smolt run from the rivers to the sea in those years to have been a failure, and one is left to conjecture that "unfavourable factors in the sea caused the destruction of the main body of smolts which descended." With most of our food fish from the sea, the abundance of future stocks is probably determined at a very early stage of the fish's life—during the first year at any rate, as shown by the successive predominance of one-year's stock from year to year in the catches. It is easy to imagine factors which may bring about heavy mortality when the fish are at a young and delicate stage, or that may even curtail spawning efforts, but the salmon are already sturdy grown fish by the time they enter the sea, and, barring excessive depredation by enemies, it is difficult to suggest a reason for their non-return.

#### Cattle Diseases in Australia.

AFTER considerable delay, arrangements have now been completed by the Australian Council for Scientific and Industrial Research for the carrying out of research work into cattle diseases in northern Australia. The Empire Marketing Board is generously meeting half the cost, up to a maximum of £5000 per annum, the Queensland Government is providing £1000 annually

and is making available its station at Townsville, the cattle industry of the State will provide £2000, to be raised by a compulsory annual levy of 1s on every hundred head of cattle other than dairy herds, the Queensland Council of Agriculture has offered £300, and it is hoped that the meat exporters will provide the balance. Dr A. W. Turner will be in charge of the station, with Dr John Legg as chief assistant. In pursuance of the policy of linking together work in different parts of the Empire by personal contact between investigators, Dr Legg is at present in South Africa studying the problems and organisation of the Veterinary Research Institute at Onderstepoort.

#### Germ of Infantile Paralysis

PROF. FREDERICK EBERSON, director of clinical laboratories and research at the Mount Zion Hospital, San Francisco, announced at the recent meeting of the American Association for the Advancement of Science that he has succeeded in cultivating the virus of poliomyelitis (infantile paralysis) in a special culture medium, and in reproducing the disease in the monkey by inoculation of the culture. The virus has long been known as an invisible and filterable one, in which state it is present in the brain and spinal cord of the patient, but in the culture it is claimed that it becomes larger and assumes a form which is just visible microscopically.

#### Announcements

WITH the year 1931, Prof. Luigi Palazzo closed his long and valued service as director of the Central Office of Meteorology and Geophysics at Rome, in which he followed the late Prof. Pietro Tacchini thirty years ago. With his work as director, he also combined the guidance of the Italian Seismological Society. He is succeeded by Prof. Emilio Oddone, until lately the head of the Geophysical Section of the Central Office. Two months earlier, Prof. G. Agamennone also retired from the directorship of the Royal Geophysical Institute of Rocca di Papa, to which he was appointed thirty-two years ago after the death of Prof. M. S. de Rossi.

IN view of the disturbed economic and financial conditions that prevail in Europe and America, the Council of the Institute of Metals has found it necessary to postpone this year's meeting, which was to have been held in the United States and Canada next autumn. The meeting had been planned with the close co-operation of the American Institute of Mining and Metallurgical Engineers. The Council's suggestion that the meeting be postponed was sympathetically received in America, and the assurance has been made that the members will be welcome at such later time as may suit their convenience.

MESSRS. Watson and Sons (Electro-Medical), Ltd., Sunic House, 43 Parker Street, Kingsway, W.C.2, have issued a booklet containing a description of their apparatus for, and full details of, 'surgical diathermy'. This is a procedure by which a high-frequency alter-

nating current is concentrated at a small electrode in the form of a short knife edge, so that a small 'cutting' arc is produced, which takes the place of the scalpel or knife ordinarily used in surgical operations, burning instead of cutting through the tissues.

A COLLECTION of collotype reproductions of early English county maps is announced for immediate publication by the Royal Geographical Society. Twenty-one sheets from the collections of the Society have been chosen to represent the chief cartographers and the engravers employed by them. The reproductions will include specimens of the work of Saxton, Symonson, Camden, Speed, and others, with notes by Mr. E. Heawood.

MESSRS. G. Bell and Sons, Ltd., announce the forthcoming publication, in a limited edition, of the diary of Michael Faraday, covering Faraday's experimental work between the years 1820 and 1862. The diary will be issued in seven volumes. Messrs. Bell also promise an account of Prof. Donnan's experiments with membrane equilibria, and the discoveries resulting from them. The author is Dr. T. R. Bolam, and the title of the volume "The Donnan Equilibria."

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A lecturer in electrical engineering at the Swindon Technical College—The Principal, College, Swindon (Jan. 12). A Goldsmiths' professor of metallurgy in the University of Cambridge—The Vice-Chancellor, The University, Cambridge (Jan. 16). An assistant master at the Bolton Municipal Technical College, for chemistry and physics—The Director of Education, Education Office, Nelson Square, Bolton (Jan. 16). An assistant lecturer in engineering at the Brighton Technical College—The Secretary, Education Offices, 54 Old Stene, Brighton (Jan. 16). An advisory officer in agricultural economics at the Edinburgh and East of Scotland College of Agriculture—The Secretary, Edinburgh and East of Scotland College of Agriculture, 13 George Square, Edinburgh (Jan. 18). An assistant curator in the Raffles Museum and Library, Singapore—The Director of Recruitment (Colonial Service), 2 Richmond Terrace, Whitehall, S.W.1 (Jan. 30). A works superintendent and chief engineer at the Manchester Municipal College of Technology—The Registrar, College of Technology, Manchester (Jan. 30). A pathologist in the Public Health Department of the Corporation of Glasgow—The Town Clerk, City Chambers, Glasgow (Feb. 1). A medical man for research work under the British Empire Leprosy Relief Association (Indian Council), in collaboration with the Calcutta School of Tropical Medicine and the All-India Institute of Hygiene—The Honorary Secretary, British Empire Leprosy Relief Association (Indian Council), Talkatora Road, New Delhi, India (Feb. 29). A male assistant superintendent of traffic in the London Telephone Service, and a male assistant traffic superintendent in the Provinces, G.P.O.—The Secretary, Civil Service Commission, Burlington Gardens, W.1 (March 3).

#### Thermoclines in Tropical Lakes.

THE thermocline is a feature of most temperate lakes during the summer months, and is normally destroyed during the winter by a complete overturn of the water, due to cooling at the surface. Little work has been done, however, on such conditions in equatorial lakes, where there is no marked seasonal difference in temperature.

F. Ruttner<sup>1,2</sup> has recently published detailed work on a series of lakes in Java, Sumatra, and Bali. As a general rule, in the smaller lakes of the order of 1-2 square km (surface area) he found well-marked thermoclines at depths of 2-8 metres. In larger lakes, layering of the water was less marked. In Lake Toba, in area about 1000 square km, the largest lake examined, he found no layering in the upper 20 metres, but a thermocline of a more gentle gradient at a depth of 25-70 metres was detectable. Ruttner concludes that wind is the important factor in preventing the development of thermoclines, and that therefore in the larger lakes, where winds have greater effect, thermoclines are less evident, their presence or absence being quite independent of the depth of the

FIG 1

lakes. In a few cases he was able to observe the development of a thermocline during the course of a few days in lakes which were previously mixed by heavy winds. He considers such mixing by wind to be comparatively rare, the stable condition being that of layering with a well-marked thermocline near the surface.

After two expeditions studying limnological problems in the African equatorial regions, we can say that no thermoclines are developed in the following lakes,

all of which are deep enough to produce either of the types described by Ruttner: Lakes Rudolf and Naivasha in Kenya, Lake Bunyoni in Uganda, and the Victoria Nyanza. Our conclusions are derived from a large number of observations on temperature, alkalinity, hydrogen ion concentration, and phosphate content at different times of the day and night. As a general rule, the water from surface to a depth of two or three metres heats up several degrees during the day, and complete mixing takes place at night, so that from midnight onwards the temperature curve

FIG 2

is vertical or even reversed in the upper few metres, as illustrated in Fig. 1 for Lake Naivasha.

These results confirm Ruttner's conclusions with regard to area and wind mixing, since all of those lakes mentioned are of the large type, with areas of more than ten square km, and range up to the enormous area of Lake Victoria. But the wind effect, if responsible, produces even greater mixing, in that no thermoclines were detected at any depth.

In Lake Edward, however, a large rift lake in Uganda with a depth of 117 metres, a very marked thermocline was found at the considerable depth of 40-60 metres. This is illustrated in Fig. 2. Lake Edward has an area of about 1500 square km, and its surface is much disturbed by winds, so that there seems no reason why a thermocline should develop there and not in Lake Rudolf or Lake Victoria. Fig. 2 shows that the upper 40 metres of Lake Edward would constitute a lake similar to Lake Naivasha with a regular heating and cooling of the upper three or four metres, suggesting that the thermocline from 40 metres to 60 metres is not due to the ordinary sun-heating at the surface. The water below the thermocline smelt strongly of hydrogen sulphide, that of the epilimnion

was odourless. The only explanation that we are able to offer for this remarkable thermocline of Lake Edward is that the heavy layer of more saline water in the hypolimnion has been introduced by rivers from the surrounding volcanic regions or from underground sources, and is prevented from mixing with the epilimnion owing to its greater density. We should suggest that the thermocline found by Ruttner in large lakes, such as Lake Toba, may also be of this nature and not a true temperature thermocline.

### Anomalous Scattering of $\alpha$ -Particles by Hydrogen and Helium

It is well known that when light is scattered by an object small compared with the wave-length, the scattered wave is spherically symmetrical. Similarly, in the wave mechanical treatment of the scattering of  $\alpha$ -particles by hydrogen and helium, the ' $\alpha$ -particle wave' scattered by the nucleus will differ from that scattered by a Coulomb field only by the spherically symmetrical wave scattered by that region (small compared with the wave-length of the incident  $\alpha$ -particles) where the interaction energy differs from the Coulomb value. Thus, without any specific model of the nucleus, we deduce that the anomalous scattering at a given velocity should be expressible in terms of a single parameter only, which determines the amplitude of this spherically symmetrical wave. Denoting by  $R$  the ratio of the number of  $\alpha$ -particles scattered through an angle  $\phi$ , to the number predicted by the inverse square law, it is shown in a recent paper<sup>1</sup> that, for scattering in helium,

$$R = \frac{\text{cosec}^2 \phi e^{-i\alpha \log \sin^2 \phi} + \sec^2 \phi e^{-i\alpha \log \cos^2 \phi} + 2i(e^{2i\alpha K} - 1)/\alpha}{\text{cosec}^4 \phi + \sec^4 \phi},$$

where  $K$  is the single parameter referred to, and  $\alpha = 8\pi e^2/vh$ ,  $v$  being the velocity of the incident  $\alpha$ -particles. A slightly simpler formula of the same type is found for scattering in hydrogen.

The experimental value for  $R$  at one given value of  $\phi$  and  $v$  determines  $K$  for that velocity, and the formula will then predict  $R$  for other angles. It has been found that the formula gives good agreement for the angle distribution in both helium and hydrogen, accounting even for the anomalous scattering at small angles, as is illustrated in the accompanying tables.

#### SCATTERING IN HELIUM

$v = 1.73 \times 10^9$  cm/sec  $K = 1.65$

| Angle ( $\phi$ )            | 10°  | 34° | 45°  |
|-----------------------------|------|-----|------|
| $R$ (calculated)            | 0.62 | 3.8 | 8.0  |
| $R$ (observed) <sup>2</sup> | 0.56 | 3.6 | 8.0* |

#### SCATTERING IN HYDROGEN

$v = 1.84 \times 10^9$  cm/sec  $K = 0.96$

| Angle ( $\phi$ )            | 0°-10° | 10°-15° | 15°-20° | 20°-21°-31°-2' | 30°-40° | 40°-50° | 50°-60° |
|-----------------------------|--------|---------|---------|----------------|---------|---------|---------|
| $R$ (calculated)            | 42     | 43      | 39      | 29             | 17      | 7.8     | 2.4     |
| $R$ (observed) <sup>3</sup> | 44     | 50      | 48      | 29*            | 13      | 7       | 1.4     |

\* The values marked with an asterisk were used to determine  $K$ .

No 3245, Vol 129]

If the values of  $K$  are calculated for two or more different velocities, they can be used to determine a model for the nuclear field. This model is spherically symmetrical and is of the type already postulated by Gamow to account for radioactive phenomena. Thus the wave mechanical solution of the scattering problem avoids the difficulty encountered by classical mechanics whereby the anomalous scattering at small angles required a nucleus with different properties in different directions.

### Nuclear Spin and Hyperfine Structure in Band Spectra.

RECENTLY, S. Mrozowski<sup>1</sup> has found that the band lines in the spectrum of mercury hydride (HgH) are split into several narrow components of constant or nearly constant separation (~0.02 Å). The bands investigated belong to a sequence  $v' = 0, v'' = 0, 1, 2, 3$  in the transition  $^2\Pi_{1/2} \rightarrow ^2\Sigma$ . Apparently the approximate formula for the isotope effect in band spectra,  $\Delta\nu_i = \delta(\frac{1}{2}\nu_{\text{osc}} \pm \nu_{\text{rot}})$ , fails completely to explain this case, and so Mrozowski concludes that the separation may be interpreted as a hyperfine structure in a more restricted sense, that is, it is caused by the magnetic or electric constitution of the atomic nuclei.

The isotope formula above, however, is not applicable to this case, the normal state  $^2\Sigma$  forming a unique example of an unstable molecule. The following figures on the vibrational effect, calculated with the aid of the more correct formula of Birge,<sup>2</sup> may be taken as an evidence for this:  $\Delta\nu_{\text{osc}}(\frac{2}{3}, \frac{2}{3}) = +0.017, -0.031, -0.049, -0.026$  cm<sup>-1</sup> in the (0, 0), (0, 1), (0, 2), (0, 3) bands respectively. In the lines investigated by Mrozowski, the rotational isotope effect is predominant, but using Birge's formulae, I find a reasonable agreement with his data. Thus, the arguments for a nuclear spin effect in the mercury hydride bands considered are of little weight. It may also be mentioned that R. Rydberg,<sup>3</sup> analysing the ultra-violet spectrum of mercury hydride with a spectrograph of high resolving power (~300,000), found a fair agreement between the observed and the calculated isotope effect.

Investigating the band spectrum of bismuth hydride (BiH), Mr. A. Heimer and I had good reasons to search for an eventual hyperfine structure, arising from the high nuclear spin ( $i = 9/2$ ) in the bismuth atom. A band system  $^1\Sigma^* \rightarrow ^1\Sigma$ , already reported,<sup>4</sup> showed no effect, the lines being extremely sharp. However, pursuing the analysis of a  $^1\Sigma^* \rightarrow ^1\Pi$  system in the red part of the spectrum, a small but distinct broadening of the first few lines in the series was observed and can be interpreted as an effect of the nuclear spin in bismuth.

The rôle played by the nuclear spin in the vector model of a diatomic molecule is analogous to that of the spinning electron in Hund's cases  $a$  and  $b$ . The energy of interaction between nuclear spins and the electronic system in the model of fixed centre is then given by  $(a_1 i_1 + a_2 i_2)A$ ,  $a_s$  and  $i_s$  denoting the coupling factor and the spin component along the figure axis of the molecule, while the mutual interaction between both spins,  $a_{12} i_1 i_2 \cos(i_1 i_2)$ , is omitted on account of its smallness. Accordingly, the hyperfine structure of electronic terms is limited to the cases  $\Lambda > 0$  ( $\Pi, \Delta, \Gamma$  terms),  $\Sigma$ -terms showing no effect. In the rotating model this coupling will break down as  $K$ , the quantum number of rotation, increases.

From the observed doublet separation in terms of one-electron molecules ( $\text{ZnH}$ ,  $\text{CdH}$ ,  $\text{HgH}$ ) the strength of the magnetic field, induced by the rotation in  $\text{BiH}$ , may be estimated, and it was found that a complete Paschen-Back effect appeared already for  $K > 3$ , causing the disappearance of the hyperfine structure. This behaviour of the model corresponds to the observations noted above. For large  $K$ -values (case  $b'$ , also including  $^1\Sigma$ -terms) a kind of rotational hyperfine structure should appear, due to an orientation of the nuclear spin to the axis of rotation. In  $^1\Sigma^+ \rightarrow ^1\Sigma$  the calculated width of lines due to this effect,  $\sigma_{\text{H}} g_i$  ( $i_K = +i, i-1, -i$ ), amounts to  $\sim 0.02 \text{ A}$ , which, however, is still too small to be distinguished from other factors governing the line width. It would appear from what is said above, that the  $\text{BiH}$  molecule is not a favourable one for such observations, lighter molecules are to be preferred. I also wish to emphasise that my interpretation of the effect is not observed, the hyperfine structure of the band lines not being resolved.

In addition, we must take into consideration that in some atoms deviating properties in the electric field of their isotopes have been observed, as clearly indicated in the case of neon. It is difficult to overlook the molecular effect resulting from this factor. Investigations are being pursued on both sides of this problem.

#### Significance of Velocity Measurements in Relation to the Benzene Substitution Problem.

From the results obtained by Holleman,<sup>1</sup> Huckel<sup>2</sup> has calculated the relative action constants and the differences between the energies of activation for the nitration of certain benzene derivatives in the ortho, meta, and para positions. The energy of activation for the ortho position is found to be greater than that for the para, and at the temperature used the amount of ortho derivative formed is smaller than that of para in the case of chlor- and brom-benzene, and the exception found in the case of toluene may be met by allowing for the double opportunity of ortho substitution as compared with that of para. These results are interesting from the point of view of steric hindrance. The equality of the action constants taken in conjunction with the facts given above shows that the lower rate of reaction observed for the ortho position is not due to steric hindrance acting on an activated molecule but to an actual paucity of activated molecules due to a difference in activation energy.

The close connexion between substitution problems and the reactivity of substituents attached to the benzene nucleus encourages me to report here the results of some experiments on the velocity of reaction between ortho, meta, and para toluidines and benzyl chloride. I have found that the energy of activation of the ortho compound is distinctly higher than that for the para compound, so that here, as in the case of direct substitution, the lower rate of reaction is not due to steric hindrance acting on activated molecules but to a paucity of active molecules. The steric effect, then, of the methyl group in the above case acts directly on the nitrogen atom by increasing the value of the energy necessary to bring it to the activated state. There is thus apparently a sort of co-ordination between the methyl group and the amino group, of a

kind possibly similar to that postulated by Sidgwick in similar cases.

Where three atoms or groups,  $A$ ,  $B$ , and  $C$ , are present in the vicinal or 1 2 3 positions, then if  $B$  is exerting an effect of this kind on  $C$  the presence of  $A$ —if its demand is greater than that of hydrogen—by sharing and so reducing the effect of  $B$  may raise the reactivity of  $C$ , this kind of effect was observed by Menschutkin in the case of vicinal  $o$ -xylydine. Other evidence of something in the nature of direct chemical interaction between the methyl and amino groups in ortho toluidine and its derivatives is the way in which ortho toluidine frequently imitates the behaviour of secondary bases and monoalkyl derivatives imitate tertiary bases. To return to the general case, when  $A$  or  $C$  is a hydrogen atom, the case reduces to the substitution of a disubstituted benzene derivative.

A vicinal effect of a different kind was observed by Holleman<sup>3</sup> in the case of 1 nitro 2, 6 dichlorobenzene, which may possibly be explained by a sharing of the activating effect of the nitro group.

There is, however, another point worthy of consideration. If the action constant were really a function of the form  $ae^{-b/T}$  then the effect of a variation in  $b$  would only be shown in the so-called energy of activation, the variation in which might be only partially due to a change in the real energy of activation. In the case of ortho toluidine, for example, the life of the activated amino group—which would presumably affect the action constant—might be appreciably affected by the ease of interchange of activation energy between the amino group and the adjacent methyl group, and if the probability of this interchange were of the required form then the observed energy of activation would contain a disguised 'action constant' term. It would appear that the question of the factors governing the lives of active molecules is one of primary interest in this connexion, a kind of molecular insurance office is, in fact, required.

I may add in conclusion that the activation energy of meta toluidine was of the order predicted by the Lapworth-Robinson hypothesis, and that these experiments will be resumed shortly.

#### Hall Effect and Superconductivity.

THE Hall effect of the so-called electronic semiconductors is usually found to be comparatively very large. All the semiconductors investigated up to the present time obey this rule, with the exception of lead sulphide ( $\text{PbS}$ ), for which the experimental data vary from one sample to another. For example, according to van Aubel<sup>1</sup> and Heaps,<sup>2</sup> chemically pure lead sulphide has a very small Hall coefficient, while the Hall constant of the natural lead sulphide (galena) may (according to investigations by A. Smith<sup>3</sup> and Heaps<sup>2</sup>) reach values as large as 254.

We have studied the Hall effect of copper sulphide ( $\text{CuS}$ ) prepared by exposing a copper plate to sulphur vapour.<sup>4,5</sup> The Hall coefficient was found to be less than  $10^{-3} \text{ c.g.s. units}$ .

It is well known that copper and lead sulphides are semiconductors which belong to the class of superconductors. It was natural to consider the question whether the small values of the Hall coefficient may be related to the existence of superconductivity.

The experimental data on the Hall effect in superconductors seem to show that this correlation really

exists In the accompanying table, the experimental values of the Hall coefficient  $R$  for superconductors at room temperatures are recorded In the last column the products  $R\sigma$  (where  $\sigma$  is the conductivity at the same temperature) are given, the figures here are not very precise, because the corresponding quantities were not always measured on the same sample We include in this table similar data for a lead-bismuth alloy (20 per cent bismuth) investigated recently in this laboratory

|                                |                   | Transition point | $R \times 10^5$      | $R\sigma$ |
|--------------------------------|-------------------|------------------|----------------------|-----------|
| Metals super-conductors        | Hg (solid)        | 4.22             | <2                   | <1        |

|                                | Mg                |                  | 90                   | 207       |
|                                | Zn                |                  | 104                  | 181       |
|                                | W                 |                  | 118                  | 225       |
| Superconductor                 | Pb-Bi (20% Bi)    |                  | <20                  | <5        |
| Compounds super-conductors     | CuS               | 1.6              | <100                 | <30       |
|                                | PbS               | 4.1              | 800                  | 8.5       |
| Compounds non-super-conductors | Mo <sub>2</sub> S |                  | $2.6 \times 10^8$    | 1400      |
|                                | Ag <sub>2</sub> S |                  | $0.6-50 \times 10^8$ | 50-275    |

As can be seen from these data, the superconductors show usually a relatively small value of  $R$  and especially of  $R\sigma$

We are investigating now the validity of this rule for other superconductors We reserve the discussion of the figures given in this note and the consideration of the theoretical conclusions which follow from this correlation for a detailed account which will be published soon in a new periodical entitled *The Physics of the Soviet Union*

We have to thank Dr. Dorfman for his helpful discussion of our work

#### Reactions of Horizons in Tropical Soils.

THE reactions of a large number of samples carefully taken at different depths in the profiles of red soils which cover such large areas of south-central Africa have been determined in this laboratory When the pH values of samples taken from a pit dug in undisturbed virgin soil are plotted against the depth, almost perfect curves are invariably obtained, there

being generally a depth of from two to three feet at which the maximum acidity is obtained This is generally coincident with the depth at which there is a tendency to form a pan both in lateritic, true red, and immature red loams, and also in the ferruginous red loams described by Marbut and Shantz In the latter soils, indeed, the pan is associated with definite concretions of hydrated sesquioxides

Further results with samples from older cultivated lands generally show the highest point of acidity to be much nearer the surface This is not surprising when the erosivity of red loam soils is considered and that often a quarter of an inch of soil has been removed in a

FIG 1

season by surface run-off and collected in large pits in Nyasaland

There has been found in these studies a general correlation between pH values and figures for average rainfall, the highest acidity being found in the tea belt of Mlanje

It has been further noticed in lower horizons of certain soils that a second point of maximum acidity is reached This may, however, be associated with abnormal movement of underground water during the wet season

It is suggested that these studies have a distinct bearing on the accumulation of compounds of iron, alumina, and manganese at certain horizons in tropical soils There are strong indications that iron bacteria play an important part in the movements of such compounds and in the formation of pans

### Liquid Drops on the Same Liquid Surface.

DR. M. KATALINIĆ has described a method of producing floating drops of clean water on a water surface by delivery from a suitably situated jet.<sup>1</sup> Such drops must owe their existence to the stability of the film immediately beneath them, that is, the thickness-coefficient of the surface tension of the film over a suitable range must be negative, a characteristic of all stable films such as those of soap. Therefore a drop of soap solution should be stable on a water surface, the hydrophobic ends of the soap ions in the surface being directed outwards, and we were able last August to produce such drops of any diameter up to about 1 cm. by simply dipping a piece of soap (any kind) in water and allowing the drops to fall off it on to the surface from a height of about 1 cm. It is best to draw the soap down in a sweeping curve into the water and then out. In this way the floating drops are propelled forward and travel for distances up to quite 1 metre, if they are not too large. The very large drops last for scarcely one second, but the smaller ones for much longer. We experimented in a large tank of rain water illuminated by the sun, and interference colours were easily observed in the film beneath the drops. Later we obtained the same results in a beaker of distilled water, or even in tap water. The observations we made were, in the main, the same as those recorded by Dr. Katalinić.

Our main object in this communication, however, is to record an observation which to us is new, namely, that in addition to the floating drops, there are often produced, but in much smaller numbers, drops of about 1-4 mm diameter which sink to a considerable depth and slowly rise again, coming to rest immediately underneath the surface. The soap film surrounding these drops is evident by the interference colours observed. They are stable for at least a minute, although they immediately burst on being touched, for example, with a clean platinum wire. They occasionally contain a minute air bubble of about 0.1 mm diameter.

We are of the opinion that these submerged drops are formed by the drop of soap solution sinking into and getting encased entirely in the main bulk of the water, because occasionally, on slowly arriving upwards at the surface, they break through and eject their own contents some millimetres above the surface, in the form of a drop which bounces several times on the surface before coming to rest and ultimately coalescing. We recently found that these submerged drops are easiest obtained in tap water.

### A New Method of Investigating the Modes of Vibration of Quartz Crystals

A NEW method of investigating the modes of vibration of quartz crystals has arisen out of the use of E. P. Tawil's<sup>1</sup> development of Topler's *Schlieren* method. Tawil was able, by utilising variations of refractive index, to photograph stationary or progressive supersonic waves in air.

In this experiment, if an accurately worked quartz crystal is set up in the incident light-beam, it is possible to orientate the crystal so that the light transmitted through it is undeviated, consequently, if the crystal is not oscillating, the whole of the field will appear dark when viewed through the telescope.

As soon as the crystal is set oscillating it will be found that certain parts of the crystal will light up, leaving in most cases a pattern of dark bands. If a fundamental mode is used, the appearance of the system will be as shown in Fig 1, A, if a more complex vibration is obtained, a correspondingly complex pattern results, as shown in Fig 1, B.

It is clear that those parts remaining dark are not giving any deviation of the incident light, and consequently represent nodal lines. However, the interpretation of the results will be complicated by the

FIG 1

fact that the pattern is probably the mean result of all figures in all planes perpendicular to the light-beam.

The method appears to possess these advantages:

(1) The effect is easily obtained even with low intensities of oscillation.

(2) The result is readily photographed.

(3) The effect is one of black-and-white contrast and consequently stands out well in cases where a coloured field might confuse the result.

In short, it seems that this additional method of examining the modes of vibration of quartz plates will, when combined with a polarised light method, give very useful results.

### An Electrostatic Explanation of the Phenomenon of Flotation.

THE explanation of the flotation processes with the aid of the cataphoretic and electroendosmotic potentials has failed completely. These potentials play an important part at a distance from the geometrical interface of the phase only.<sup>1</sup> There are, however, suggestions in the literature<sup>2</sup> that ideal chemical electrodes should have a positive electrostatic potential in water and the dielectrics a negative one. This suggestion has important consequences. Emulsions of dielectrics in water will wet unattackable electrodes immersed in water but not attackable electrodes which are coated with dielectric oxides (hydroxides) in water. The wetting must, however, reduce the positive charge of the unattackable electrode, and it is expected that the wetting will not take place on attackable electrodes coated with a dielectric hydroxide, as for example, zinc. This is actually observed.

The irreversible electrostatic potential on the interface solid-liquid was measured with the aid of a Lindemann, or Leiss Perucca electrometer of small capacity. A platinum electrode, a galena electrode, an Acheson graphite electrode for spectroscopic purposes made by Messrs Adam Hilger, Ltd, and a zinc electrode, were immersed successively in 50 c.c. of 0.002 N potassium chloride of pH 7.5 and their potential was measured against a 0.002 N calomel

electrode Adding to the 50 c.c. of 0.002 N potassium chloride an emulsion of 4 gm. terpineol and 4 gm. potassium xantogenicum in 1000 c.c. of 0.002 N potassium chloride of the same pH, namely, 7.5, there was found a remarkable difference in the behaviour between the unattackable electrodes, platinum, galena, and graphite and the attackable zinc. Zinc changes its potential very little, the indifferent electrodes mentioned above, however, show a very marked fall of the potential as is shown in Fig. 1.

FIG. 1

The first portion of 0.02 c.c. of the terpineol and potassium xantogenicum emulsion has a great influence on the potential of the electrode in spite of the fact that the emulsion loses its character at that dilution, and at 1 c.c. of these weak solutions has a maximum effect. Solutions of that strength are used in practice for flotation most frequently. It should be added that the electrometric measuring of the hydrogen ion concentration of physiological yeasts may be entirely spoiled if such a minute concentration as 1 in 500,000 by weight of an organic compound changes the potential of platinum so markedly.

### Nature of Liquids

PROF. G. W. STEWART<sup>1</sup> and Prof. E. N. da C. Andrade<sup>2</sup> have agreed, one in the light of X-ray diffraction experiments, and the other in the light of theoretical considerations of viscosity, that a liquid is, especially near the melting point, more akin to a solid than a gas.

It is perhaps worth while to point out that this view is consistent with what is observed concerning the specific heats of elements in the solid and liquid phases near the melting point. It is, in fact, the case that for the majority of monatomic elements hitherto investigated, the atomic heat of the liquid at constant volume is within about ten per cent of the value for the solid immediately below the melting point, and that this value is approximately  $3N_0k$  (that is,  $3R$ ), where  $N_0$  is Avogadro's number and  $k$  is Boltzmann's constant.

The value  $3R$  for the solid may be explained in terms of the three degrees of freedom of an atom, each degree of freedom contributing on the average  $\frac{1}{2}kT$  to the energy as kinetic energy, together with (if the

oscillation is simple harmonic in character) a further  $\frac{1}{2}kT$  as potential energy.

The fact that the variation of energy content with temperature in the liquid is approximately the same as in the solid, is consistent with the view that in a liquid, at temperatures not too far above its melting point, the atoms continue to execute motions which may be described as approximately simple harmonic, the contribution per degree of freedom of the potential energy to the total being still approximately equal to that of the kinetic energy, which, since it depends on squares of velocities, must have the equipartition value of  $\frac{1}{2}kT$ .

If, on the other hand, the potential energy of atomic motion in a liquid were negligible compared with the kinetic energy, the atomic heat at constant volume would fall to the value appropriate to a monatomic gas, namely,  $\frac{3}{2}R$ . L. G. CARPENTER

### Freshwater Eels in British India.

FOR some ten years now I have been collecting data regarding the occurrence or absence of freshwater eels—of the genus *Anguilla*—in the fresh waters of the world, and we seem on the whole to have cleared up this matter. Yet there are two regions where some uncertainty still reigns and, curiously enough, British India is one of them.

I have seen specimens of freshwater eels from the greater part of India, from Burma to Bombay, but whether they occur north of Bombay, and especially in the River Indus, I have not succeeded in determining, neither through the available literature nor through questions. Yet it would be astonishing, it seems to me, if there were no information on this subject from one of the principal river systems of the Old World.

The question is of considerable importance for the understanding of the distribution of the freshwater eels, which spawn in the Indian Ocean. It would be of interest, therefore, if Indian zoologists, or others concerned with the fisheries there, could take up this question and discover whether freshwater eels of the genus *Anguilla* are really present or wanting in the River Indus.

### The Raman Band of Water.

THE peculiar feature of the Raman band of water which I observed during my experimental researches<sup>1</sup> may be produced, or at least essentially modified, by a particular and unexpected action of the spectrograph.

The Hilger E1 spectrograph used by me being provided, immediately behind the slit, with a total-reflecting prism of crystalline quartz, that is, with a double-refracting system, we are making use of an optical arrangement that may cause interferential phenomena, if the incident light is even partially polarised.

Under such conditions the use of the above-mentioned spectrograph is inadvisable. G. BOLLA

Physical Institute of the Royal University,

<sup>1</sup> NATURE, Sept. 26, 1931.

## Research Items.

**Prehistoric Sind and Sumeria**—Mr Ernest Mackay publishes in *Antiquity* for December some further links between Mohenjo-daro and ancient Sumeria, which he is able to add to those given in the recently published "Mohenjo-daro", edited by Sir John Marshall, as a result of the examination of material added to the Baghdad Museum since he left Iraq. Red carnelian beads with a white design found in graves at Ur are identical with those from Sind, the latter probably being a local copy of an imported head. Other examples of decorated carnelian beads link the two civilisations, but at Mohenjo-daro they were probably imported and were greatly valued, as is shown by the fact that they were copied in steatite, the red ground being produced by a burnished hæmatite paint. Persia may have been the original source and may also have supplied Russia. A peculiar bead, rhomboidal in section, of which the long sides are notched, is also found at Ur and Kish, where it is dated at about 3100 B.C. They may be copied from sickle flints, and in Sind were probably imported from Sumeria. Terminals in gold, copper, or faience are frequently found at Mohenjo-daro. Though not yet found in Sumeria, they occur at Byblos, dating from the Fourth Dynasty of Egypt. Hollow gold terminals exactly resembling these have recently been found at Gizeh (2900-2750 B.C.). A copper blade found at Mohenjo-daro in one of the upper layers exactly resembles one from Kish, except that the latter has a longer tang. Cubical dice, tetrahedral gamesmen, and pottery rings, thought to belong to a game, have been found at Mohenjo-daro and in Sumeria. The framed Greek cross and the swastika occur in both areas, though a swastika found at Kish may have been made locally for an Indian resident. Other resemblances noted are feeding-cups with projecting spouts, beads capped with gold, perforated vessels, hollow animal masks in pottery and metal, and the narrowing of the eyes in certain human figures.

**Rhythmisation in a Motor Task**—At the meeting of the British Association on Sept. 28 a very interesting paper was given to Section J (Psychology), by Mr D. W. Harding, on the part played by rhythm in learning typewriting. Observations were made on experienced typists practising an unfamiliar word until they could type it at their normal high speed. In typing, owing to the nature of the keyboard, the rhythms that may occur are more complex than those hitherto studied in G. E. Muller's experiments in memorising. The experiments were carried out with an ordinary portable typewriter, but in place of the usual paper for receiving the impressions, a paper tape moving through the machine at a constant rate was substituted. The subjects typed in the usual way, but, as the tape moved continuously, any difference in the time intervals between letter-strokes was recorded as a difference in spacing on the tape. Each subject's work was measured for uniformity by estimating the deviation from uniformity of the time-interval between each letter-stroke and the next, and for consistency, as represented by the coefficient of variability, from repetition to repetition of the ratios in the word. This allowed the sameness of the rhythm to be measured even though the tempo might not be the same. The most striking result that appeared was the relation between rhythmisation and capacity for speed, those subjects who tended to maintain uniform time-intervals between successive letters being the slowest. As the learning of movements plays such an important part in education and also in many

industrial processes, this very careful and original study is of considerable value and deserves to be carried further.

**Sexual Selection and External Appearance**—O. L. Tinklepaugh, in the *Journal of Mammalogy* for November (p. 430), records a case in which a male of the rhesus macaque (*Macaca mulatta*), kept along with a female crab-eating macaque (*M. irus*), plucked and bit off the long hairs of the eyebrows and cheek-tufts of his companion, often leaning back and surveying her as if evaluating results. The suggestion is made that he was modifying her appearance to suit his taste, and it may be noted that the rhesus is far less hairy about the face than the crab-eating macaque, so that it would appear that the male was here trying to make his alien mate conform to the appearance of females of his own species. A similar case in birds occurred at the London Zoological Gardens during this century, in which a male ocellated turkey (*Meleagris ocellata*) plucked out the crest of a Burmese peahen (*Pavo muticus*) which had become attached to him in spite of the presence of a male of her own kind, thus reducing her head to the unadorned state of that of a hen turkey.

**Abnormalities in the Frog's Blood-vessels**—Dr C. H. O'Donoghue (*Trans. Roy. Soc. Edin.*, vol. 57, pp. 179-224, 1931) describes forty-eight hitherto unrecorded abnormalities in the blood vascular system of *Rana temporaria*, summarises the abnormalities previously recorded, and discusses the general significance of each type of abnormality. One example of an imperfectly flexed heart is described, which, it is suggested, results from the retention of the dorsal mesocardium. In one frog the right systemic aorta was absent, posterior to the point of origin of the subclavian artery, in four other frogs accessory pulmonary arteries were present as branches of the coeliac-mesenteric artery to one or both of the lungs. In each of nine examples a transverse anastomosis was present between the two external jugular veins, and in the majority of these the right anterior caval vein was missing. Six abnormalities of the anterior abdominal vein and seventeen abnormalities in the posterior cardinal, posterior caval, and renal-portal veins are noticed, which are explicable in the light of the embryonic history of the respective veins. Abnormal accessory pulmonary veins arising in the lungs and emptying into some factor of the hepatic portal system are described in six specimens. A consideration of some of the abnormalities reveals homologies between certain of the main veins in the Anura and in the elasmobranchs. This paper will be very useful for reference in all laboratories where the blood vessels of *Rana temporaria* are examined in any detail and where, therefore, abnormalities are almost certain to come under observation.

**Indian Horse Flies**—Part 3, Vol. 1 (September 1931), of the new *Indian Journal of Veterinary Science and Animal Husbandry*, among other articles, contains part 14 of a "Veterinary Entomology for India", by T. B. Fletcher and S. K. Sen. It deals with the Tabanidæ or horse flies, of which about 135 Indian species have been described. The article is illustrated with an admirable coloured plate depicting twenty-four species of various genera. One of the most remarkable insects figured is *Corizoneura longirostris*, in which the 'proboscis' is one and a half times the length of the body. This fly has been observed to suck nectar from flowers, and the long

proboscis, which is actually the labium, is well adapted for scooping up nectar. The true piercing stylets are much shorter and are hidden away in the labium.

**Cultivation of Sisal**—Sisal (*Agave sisalana*) is a fibre-yielding plant of great and increasing importance in East Africa, and some account of the problems in connexion with its cultivation are given by F. J. Nutman of the Amani Research Station (*Bulletin of the Imperial Institute*, vol. 29, p. 299). Up to the present, scarcely any research has been carried out with this crop, as it has been possible to grow it profitably with a minimum of scientific knowledge, and since the plant is not an annual, field experiments are necessarily long and expensive. One of the most important physiological questions is a proper understanding of the factors influencing flowering, for after the production of the inflorescence the plant dies and no more leaves, the source of the fibre, are developed. The suggestion that flowering, or 'poling' as it is termed, occurs after the formation of a given number of leaves is rejected, but it is still uncertain whether, and in what way, soil, climate, and water relations can be correlated with this fundamental change in the plant's development. Fruiting, on the other hand, appears to be influenced by quite different factors, for although flowering is a universal phenomenon, fruit formation is confined to the highlands of Kenya. Propagation is in consequence entirely vegetative by means of bulbils and suckers, and further investigations are needed to determine if treatment of the parent can influence the after behaviour of the suckers. Other important problems arise in connexion with the drought-resisting properties exhibited by sisal, for there is a tendency to extend its culture into the more arid parts of East Africa, and under semi-desert conditions special cultivation operations appear to be necessary. In addition to physiological problems such as these, questions of agronomy and genetical interest abound, and if the sisal industry is to survive the critical period through which it is at present passing, further research is of fundamental importance.

**Origin of Witwatersrand Gold.**—Dr L. C. Graton's recent advocacy of a hydrothermal origin for the gold deposits of the Rand has stimulated a vigorous discussion, which is published in an 'Annexure' to the *Trans. Geol. Soc. South Africa*, for 1931. In all ten papers the conclusion is reached that the hydrothermal hypothesis is untenable. R. B. Young shows clearly that the distribution of gold is related to the sedimentary characters of the beds, whereas the metasomatism that has undoubtedly occurred bears no relation to that distribution. This contrast is confirmed by E. Homersham, E. T. Mellor, and J. W. Gregory. The last two of these authors and A. W. Rogers, F. E. Keep, E. H. A. Joseph, and W. S. F. Cameron give conclusive evidence that the blanket could not have been accumulated in the off-shore marine environment postulated by Graton; they favour deltaic or littoral conditions, and record many instances of contemporaneous erosion. F. E. Keep makes a good point in comparing the gold occurrences with those of genuine hydrothermal origin. E. T. Mellor, E. P. Cowles, and P. Macadam present assay results demonstrating that the amount of gold carried by the quartz veins is negligible compared with that in the pay reefs. P. Macadam also shows that the basic dykes are free from gold or contain only minute traces, and W. S. F. Cameron considers, with justification, that the gold in the quartz-veins may well have been derived from that present in the placer deposits through which they have passed. (See also *NATURE*, 127, 536, April 4, 1931.)

**Acoustic Sounding**—Commander J. A. Slee read an important paper on reflexion methods of measuring the depth of the sea to the Institution of Electrical Engineers on Dec. 2. Navigators of big ships are very anxious to read depths up to a hundred fathoms and are particularly interested in depths from two to twenty fathoms of water under the keel. Trawlers, on the other hand, need to measure much greater depths, at least as great as 350 fathoms. The vast majority of fish are bottom feeders—the surface and midwater feeders are comparatively rare. For a given locality and time of year, the best depths for various kinds of fish are known, and so it is a great boon for the fishermen to know the depth within an accuracy of about one or two per cent. The author describes the various methods of signalling, that is, of setting up an elastic wave in the water, the methods of detecting the return of the echo, the methods of disentangling the unwanted signals, and the methods of measuring the time which gives the required depth. The rate of propagation of the elastic wave varies according to the salinity and temperature of the water, the accepted extremes being 4750 ft. per second for the Baltic, which is nearly fresh, and 5100 ft. per second for the Red Sea, which is saturated. The velocity usually adopted is the average of the Atlantic Ocean, which is 4900 ft. per second. The best methods of measuring are to use some form of oscillographic device. Aural methods are not so successful, as the rush of water past the ship's skin sets up noises in any kind of receiver and, in addition, there is the question of turbulence eddies. The water is thrown out by the ship's bows and returns again at some point along her hull, where the water noises are redoubled. It is known that the position of these turbulence areas varies with the speed of the ship, with her draught and trim, but in any given case the boundaries of the patches are quite sharply defined.

**The Spin of the Photon**—The work referred to by Sir C. V. Raman and S. Bhagavantam in their recent communications to *NATURE* (Oct. 3, p. 576, Oct. 24, p. 727), from which it was concluded that light quanta had a Bohr unit of angular momentum, is described with more detail in the issue of the *Indian Journal of Physics* for Oct. 31. It appears that up to a certain point quantum theory and classical theory agree in their predictions with regard to the scattering of light, but that the finer details of polarisation and intensity can only be accounted for by means of quantum theory, with the special feature now emphasised. The experimental method which has been employed is simple in principle, the separation of the effects of the various close components of the radiation scattered from gases and liquids being made by varying the width of the slit of the spectroscope (see *NATURE*, Jan. 2, p. 22). The references in this paper to liquids, although not an obvious sequel to Sir C. V. Raman's later letter (*NATURE*, Nov. 7, p. 795), are very interesting in showing that molecules in certain types of liquids apparently have considerable rotational freedom. At the same time, in another paper in the same issue of the *Journal*, Mr. Bhagavantam has shown that the rotational fine structure of the Raman bands from a number of gases becomes diffuse above a certain rather critical pressure in each gas, and interprets this as a disturbance of the molecular spin by collisions when the frequency of rotational motion of a molecule is no longer greater than the average frequency of collisions between molecules.

**Conical Diaphragms and Sound Reproduction**—The scientific aspect of the problem of sound reproduction by means of conical diaphragms is one of commercial importance at the present time. In the *Philosophical*

*Magazine* for October, Dr N W McLachlan and G A V Sowter give the results of a fairly complete experimental research on this type of apparatus for reproducing speech and music. They have found that when the edge of a diaphragm is reinforced so as to prevent radial modes of vibration at low frequencies, the lower register appears to be missing. This is due to the enhanced output in the upper register. Thus, although the diaphragm behaves as a rigid structure at low frequencies, it breaks up at the higher frequencies. To equalise the output, therefore, it is necessary to introduce a resonant member to assist the lower register. One method of doing this is to suspend the diaphragm from an annulus of suitable material and dimensions. The annulus acts as an auxiliary diaphragm at low frequencies and improves the reproduction. The upper register can be increased by the use of coils of small mass. This suggested the use of thin sheet metal, but experiments with aluminium sheet were not successful, as a large fraction of the register lying above 200 cycles per second was relatively weak. The reproduction lacked volume and was unpleasant to listen to. This shows the difficulty in obtaining a uniform register of wide compass owing to the load on the acoustic system being small and the acoustic resonances being numerous. In the exponential horn type the acoustic loading is relatively high and gives large damping. The horn is a scientific but not at the moment an economical solution of the problem of sound reproduction.

**Rhenium Compounds**—Briscoe, Robinson, and Stoddart, in the November *Journal of the Chemical Society*, give details of some experiments on the sup-

posed thallous thioper-rhenate,  $\text{TLReS}_4$ , recently described by Feit. They show that the product so described is not a thioper-rhenate but either a mixture of thallous per-rhenate and rhenium sulphide, or almost pure per-rhenate, according to the method of preparation. The same issue gives an account, by Briscoe, Robinson, and Rudge, of a new oxide of rhenium, the pentoxide,  $\text{Re}_2\text{O}_5$ , obtained by heating rhenium heptoxide with the metal in a sealed tube. It is a purplish-red crystalline powder, being bottle-green in thin flakes with transmitted light and showing a green streak. The new oxide is insoluble in dilute or concentrated sulphuric or hydrochloric acid and in caustic potash solution, but dissolves in warm dilute nitric acid and in fused caustic potash.

**The Glass Electrode**—The *Journal of the Chemical Society* for November contains two papers by C Morton on the use of valve electrometers and valve potentiometers with the glass electrode. The arrangements of the circuits are shown and the accuracy of the instruments has been increased. The application of the valve potentiometer to differential potentiometric titration with the glass electrode is described, with some experimental details. The new feature of the valve potentiometer is an increase of sensitivity with increasing resistance of the source of electromotive force, which makes it particularly suitable for use with the glass electrode. A sensitivity of 38 microamperes per millivolt was obtained. The null ballistic valve galvanometer described had complete zero stability and high sensitivity. The sensitivity was such that an electromotive force of 0.01 millivolt operating through 1000 megohms could be detected.

### Astronomical Topics.

**Great Meteor in Southern Europe**—The daily papers reported that a meteor of unusual size was seen in Portugal on the night between Dec 28 and 29. No exact details are yet to hand, the reports describe it as greenish, three times the apparent diameter of the moon, and suggest that it may have fallen into the sea, as its light vanished with startling suddenness. It is to be hoped that it was seen by some trained observers.

**Observations of the Leonids in England**—The fact that a fair display of these meteors was seen in England by Mr J P M Prentice at Stowmarket, Suffolk, and Mr A King at Ashby, Lincs, has been already noted in this column. Fuller details are given by Mr King in the *Observatory* for December. The maximum, according to both observers, occurred rather late on the night between Nov 16 and 17. None were seen on Nov 9 and 11, one early on Nov 14, while Mr King saw eight early on Nov 18, a fair shower was seen in Iowa early on Nov 16, so that the earth takes more than two days in traversing a tolerably rich region of the swarm, though it takes only six hours in crossing the extremely crowded 'orthostream'.

The position of the radiant for the night Nov 16-17 is given as R.A. 153° 0', Decl. +21° 7', by Mr Prentice and R.A. 152°, Decl. +22° 2', by Mr King. Prof J C Adams adopted 149° 2' +23° 0' (the mean of six observers) for the 1866 display. Precession accounts for a change of +0° 9', -0° 3', the remainder is due to the perturbations of the meteors. The longitude of their ascending node, given by the above observations, is near 233° 9', which agrees exactly with the value of the node of Tempel's comet predicted in the B.A.A. Handbook for 1932.

**Cepheids and Long-Period Variable Stars**—*Scientia* for December contains an article on these stars by Mr P Doig. The two classes differ chiefly in temperature, the red stars of long period have temperatures of the order of 2000°, while the Cepheids range from 4000° (type G) to 10,000° (type A). The extreme rarity of these stars in space is pointed out; one star in a hundred thousand is a long-period variable, and the distances between them are of the order of 500 light years. The Cepheids are rarer still, accepting Shapley's distances (which are now thought to be somewhat too large), there is only one Cepheid in two million stars, and the distance between them averages 1500 light years. These figures suggest that variation of either kind lasts only for a small fraction of the whole life of a star.

Mr Doig considers that the ordinary long-period stars vary from a similar cause to the Cepheid stars, but that the super-giant Betelgeux stands outside them, probably because of its excessively low density. He favours the theory of Sir James Jeans that the Cepheids are rotating stars on the point of dividing into two. This causes a wave to travel round the star's surface, and its shape is supposed to be steeper in front than in the rear, thus accounting for the steeper rise than fall in the light curve. The long-period stars are supposed to be at an earlier and less condensed stage than the Cepheids, in both of them a liquid or quasi-liquid core is postulated. It is suggested that in Betelgeux the density may be too low for the formation of such a core. In its case the variation arises from pulsation alone, in the other cases from a combination of pulsation with the phenomena arising from an elongated nucleus in the process of dividing.

### University of Leeds. New Physics Building.

THE new physics building of the University of Leeds represents part of the rebuilding scheme made possible by generous donations from the public during the past several years. It replaces the old 'sheds', a temporary glass-roofed structure put up some twenty years ago, and part of one of the original wings in the occupation of the Department of Physics, but under the new scheme destined for demolition. These old laboratories had long been inadequate for their purpose and more than uncomfortable in use. The lecture room accommodation was scanty, the teaching laboratories weather-swept, and the research rooms unfortunately placed.

The new building occupies a quiet and unobtrusive site which is likely to be detached for some time to come, though it will eventually form architecturally an end link of the projected chain of stone-fronted buildings of which the chemical building and the Brotherton Library will shortly be prominent features. The cost of the physics building itself with equipment will approximate to £60,000. The architects were Lancaster, Lucas, and Lodge, of London.

So far as present needs are concerned, the Department caters for two hundred and fifty to three hundred undergraduates, including a total honours school of thirty to forty, with a research group of ten to fifteen working mostly on experimental topics. Allowing for expansion of these numbers on a conservative basis, a building of red brick, of about 35,000 square feet floor space, has been put up, comprising three floors and basement. Portland stone facing is used only on that small part which will be visible in the distance from the main road. The steel framework is specially oversize, and particular care has been taken that no internal walls support any appreciable part of the weight. Inside rearrangement can therefore be carried out in the future, if necessary, with no serious difficulty.

The workshop has been placed in a far corner of the basement, lit by an overhead glass roof and ventilated by a fan. The basement also contains certain research rooms, battery and store rooms, a special instrument test room, an acoustics laboratory, and a museum.

The entrance hall on the ground floor has been arranged to lead directly to the two main lecture rooms on one side and to the elementary laboratory on the other. This arrangement makes it unnecessary for the large numbers of students attending elementary lectures and laboratories to penetrate more than a few paces into the building, thus minimising the effects of wear, dirt, and noise.

The first floor carries a large L-shaped laboratory capable of accommodating a hundred students of the second and third year in individual work. On this floor there is also the honours laboratory with a capacity of about twenty students and a small lecture room capable of holding fifty.

The top floor contains a few rooms at the stair-head for general departmental use, the main floor space being given over to small research rooms, seventeen in number. In addition to the electrical and other services, a certain number of steady wall-supports consisting of monoliths built into the wall have been provided. Also horizontal sliding steel window shutters have been installed, similar to those in the lecture rooms but hand operated.

The simplest possible internal style has been adopted throughout the building, although a most pleasing effect has been attained in entrance, stairway, and corridors by clever arrangement of pillars, well-designed balustrades, and simple arches. The

stairways and the floors of main corridors are in terrazzo but elsewhere Australian jarroo wood block has been generally chosen, the result being excellent in respect of cleanliness and comfort as well as appearance.

For convenience of upkeep and ease of replacement, all services have been placed so far as possible on wall and ceiling surfaces and have been coloured distinctively. For example, lighting electricity is yellow, town supply of water is aluminium, gas is black, and so on. Electrical services comprise 200 volts alternating supply at 50 cycles single phase and two-phase from the city mains for lighting and power, together with 110 volts d.c. from a generator set in the basement. In addition, there are two large capacity batteries each giving up to 120 volts and two smaller ones giving up to 1000 volts each. These supplies are taken to the lecture rooms and to the research rooms on both top floor and basement. For convenience in running temporary leads about the building, a vertical duct runs through the building in close proximity to the battery rooms. A small compressor in the basement supplies compressed air to research rooms and lecture rooms for blowpipes, small motors, cooling, and the like. Heating throughout the building is by radiators supplied with hot water from the University boiler house. A lift and the adequately equipped workshop complete the laboratory services.

There are three lecture rooms, seating 230, 120, and 50 respectively, the two larger ones being fitted with electrically operated steel window shutters of a simple type. Ventilation is by distant-control fan, and the fittings include specially designed roller blind blackboards, air-cooled projection lanterns sunk in the lecture tables, with inclined screens built permanently into the wall and facing the audience, floodlights (motor head lamps) for blackboards and lecture tables, and an adequate supply of electricity, gas, water, and compressed air. The control of all lecture room services has been centralised on the lecture bench itself, so that the lecturer or his assistant can deal on the spot with lantern, ventilation, shutters, and lighting.

In the teaching laboratories, simplicity of arrangement and fittings has been achieved by the provision of ordinary movable tables of a standard size, and fixing all water services to outside walls wherever possible.

In place of dark rooms for optical and other experiments requiring darkness, several sets of dark cells have been provided (similar to horse 'loose boxes'), so that numbers of students can work in close proximity to each other without mutual interference. In the main laboratories, vibration-free supports for galvanometers and other apparatus requiring steadiness have been provided by casting wide ferroconcrete collars round such pillars as have their foundations in the basement. Round these collars are fitted insulated stainless steel busbars connected to 25 volts alternating electric supply. This supply is taken through a new type of electric plug which adheres to the busbars by means of small permanent magnet contacts.

Although, at the date of writing, workmen are not yet out of the building, experience has shown the great convenience and effectiveness of the arrangements.

An opening function will take place on Feb. 18, when Sir William Bragg, one time occupant of the Cavendish chair of physics in the University, will be the principal speaker.

## Annual Meeting of the Science Masters' Association

THE thirty-second annual meeting of the Science Masters' Association was held in the Imperial College of Science, London, on Dec 29-Jan 1, with evening meetings in the hall of King's College for Household and Social Science. The trade exhibition of apparatus and books, and also the exhibition of apparatus and experiments by the members themselves, was the largest in the history of the Association.

In the course of his presidential address, Dr Cyril Norwood, headmaster of Harrow School, pointed out that modern science has produced an upheaval in man's intellectual and spiritual outlook comparable to that produced by the Renaissance, and, in its material aspects, has led to a rapidly increasing mechanisation of modern life. The one effective shield against this mechanisation will be found in a remodelling of our system of education, so that it will satisfy the creative instinct of the child to do and to make, and also develop his faculty of æsthetic appreciation.

The Renaissance produced a system of education, culminating in the universities, which has persisted until recently, despite the fact that only one-tenth of the secondary school population now proceeds to the universities. The object of the older type of education was to produce specialists and to train for the professions, but in future the schools must aim at becoming training grounds for democracy. Whereas in the past the schools produced the great individual, they must now aim at the wider task of producing the great community, and our educational system must be remodelled to that end. This requires the freeing of the school certificate from the demands of university entrance.

An elementary study of any subject should result, in average pupils, in the acquirement of a sense of fact and a sense of law. Dr Norwood stated that there is nothing better for this purpose than the study of elementary science, which is admirable for training the mind in the power of discovering facts and reasoning from them, and, properly taught, should result in a clear grasp of the difference between fact and opinion, which difference, even as in Plato's time, is not apparent to the majority of people. Dr Norwood recommended the *universal* teaching of science as a necessary part of a preparation for citizenship. He suggested a course in chemistry, physics, and biology, with excursions into geography, geology, and astronomy, which should include simple elementary nature study and exact and simple measurement. Such a course would open a lot of windows in the mind of the pupil.

In welcoming the Association to the Imperial College, the rector, Mr H. T. Tizard, stated that the scientific equipment and also the general education of boys has improved beyond all bounds during the last few years. This period has seen the disappearance of both the dogmatism of the scientific man and the arrogance of the classicist. Mr Tizard is a great believer in general science as a subject for the school curriculum. The difficulty is that scientific men have not yet been able to agree upon the lines this should take, and he urged that the solution of this problem should be the most important work of the Association in the near future. He hoped that they would produce a scheme which would appeal to intelligent laymen.

Prof Jocelyn Thorpe, in his address on "The Schools and Research", directed attention to the great work which has been accomplished by such men as Shenstone, H. B. Baker, Francis Jones, R. L.

Taylor, and Tilden, all of whom commenced their researches as science masters in schools. If a science master can find time to do research in his school, it is bound to have a stimulating effect on his pupils. He invited attention specially to the advances made in biochemistry during the last few years, which have resulted in the isolation of definite organic compounds controlling the processes of life. Some of these are introduced into the body by the food we eat, others are manufactured in the body itself, but all are essential to life and health. Sometime in the future, much ill-health and disease will be eliminated by the administration of the required organic substance in the quantity necessary to correct the maladjustment. Prof Thorpe went on to discuss the importance of hormones and vitamins, and he showed specimens of the anti-scorbutic vitamin E, which has only recently been isolated from orange juice. Calciferol (vitamin D) has also been isolated after twelve years of patient research.

Dr G. C. Simpson addressed the Association on "Modern Weather Forecasting", in the course of which he gave a most lucid account of the mechanism which produces a 'warm front' and a 'cold front'.

On New Year's eve, Prof E. W. MacBride's lecture on "The Inheritance of Acquired Characters" provoked a stimulating discussion, which was continued in the Common Room, until the approach of midnight reminded Prof MacBride that he had promised to attend a New Year party.

The Television Society arranged a most valuable lecture-demonstration, in which experiments, many suitable for school use, were shown. Mr J. J. Denton, honorary secretary of the Television Society, lectured, and the experiments were shown by Capt R. Wilson, Mr A. A. Waters, and Mr R. W. Corkling.

In the trade exhibition, the exhibit of colour photography, given by the Finlay Photographic Processes, Ltd., is worthy of special notice. The most interesting feature illustrated the application of the Finlay colour process in the teaching of biology. Eighty-one lantern slides were exhibited to illustrate a first year's course in biology, the zoological subjects having been selected by Prof E. W. MacBride, and the botanical subjects by Mr J. S. Gilmour, assistant director at the Royal Botanic Gardens, Kew. Many of the slides are micrographic, the colour is remarkably accurate, and there is no doubt that the utility of these slides for teaching purposes is greatly enhanced by their being in colour. We understand that if the company meets with sufficient encouragement in its effort to furnish accurate colour slides of this description, a further series of scientific subjects will be prepared. The process itself is one that can be worked quite easily by the amateur with any size and make of plate camera. Apart from the fact that it is an entirely British process, it has certain definite advantages over any other known method of colour photography. It gives a brilliant result with a single exposure at a very high speed, and it is capable of unlimited duplication. Many of the outdoor scenes shown were taken with an aperture of 4.5 at speeds which varied from one-fiftieth to one-half of a second. It can be applied, therefore, to subjects involving movement or stay of movement.

In the members' exhibition, Mr E. G. Savage gave fascinating demonstrations of experiments on colour. These were described in detail in the *School Science Review* for October and December 1931. Mr F. A. Meier, of Rugby School, exhibited a remarkable selection of apparatus made in the Rugby School

workshops His ingenious devices are worth an article in themselves We were greatly impressed by his method of doing Kundt's experiment, using a brass tube with two thick circular plates of brass soldered at nodes a quarter of the length of the tube from each end, these plates fit between two blocks of wood on a rigid stand The cork at one end of the brass tube is stuck on by resin, so as not to constrain the vibration of the tube, and the resonance tube of glass contains no visible lycopodium until the note is obtained, when the nodes are evident as very fine lines, the position of which can be read to 0.02 cm. by a travelling microscope Mr Meier said that a few

degrees difference in temperature, such as results from turning out a gas fire in the room produces a measurable displacement of the nodes

The retiring chairman of the Association, Mr W H Barrett, of Harrow School, handled the annual business meeting with skill A resolution was passed assuring the president that the Association would support him in any steps he may take to initiate a reform of our educational system on the lines laid down in the course of his presidential address

The next meeting of the Association is to be held at the University of Bristol, on Jan 3-5, 1933, and the new president will be Prof A M Tyndall E N

### Form and Height of Clouds

THE Central Meteorological Observatory at Tokyo has recently published an illustrated account of a thorough photometric study of clouds made at the Meteorological Observatory at Mera Mera lies at the southern extremity of the Bôso peninsula, in the south-east of Japan proper, at no great distance from Tokyo The observations cover the period of two years ending on Mar 31, 1929, and were made by three members of the staff of the Mera Observatory

Although the work does not appear to have been undertaken with the solution of any particular problem in view, and might be adversely criticised on the ground that we have already too many such bulky statistical compilations relating to the weather of temperate latitudes, such criticism should be qualified in view of the fact that the information about the heights of various forms of cloud in this work is rarely based on measurements of single points in the cloud, but on so many points that an idea is given of the vertical extent of the cloud as well as of its height above the ground For example, a photograph numbered 217 in the section devoted to stratocumulus clouds, portrays a group of these clouds and alongside a key diagram with numbered points In a table underneath, the measured heights of these points are shown One of the larger fragments of cloud contains five such points, and the table shows that the lowest height was 1489 metres and the highest 1587 metres, whence we deduce a minimum of 89 metres for the vertical extent of this particular cloud The table further informs us that the mean height of the whole group was 1534 metres and the range 117 metres

The heights were obtained by two photo-theodolites of German manufacture set up at the ends of a base line 1161 metres in length—a length that should ensure a fair degree of accuracy even in the measurement of cirrus clouds, which normally occur at heights equal to about seven times the length of the base line

There is another aspect of the work which calls for favourable criticism, and that is that the quality of the photographs and the complete range of form illustrated justifies the authors in describing section VIII as a "Cloud Atlas" It is an atlas in which the full information about the heights of the clouds just described is supplemented by figures giving the mean amount of cloud on each occasion, its speed and direction of movement, and the speed and direction of the wind near the ground When telephotographic representations of cloud are given and no terrestrial object appears in the field of view, the reader is likely to have a difficulty in imagining the true appearance of the clouds, unless some device is adopted for giving the scale of the photograph In this event, a circular line might with advantage have been added in one corner of each photograph, the diameter of the circle being equivalent to about half a degree, that is, to about the diameter of the sun or moon, so that the clouds could be compared with either of these luminaries

It should be noted that in addition to the section described as a cloud atlas, there are numerous tables relating to the heights of the different clouds, and the seasonal variations of these are shown by graphs, as well as being given in tabular form

E V N

### Photocells: the Valves which operate by Light.\*

ONCE the potentialities of devices in which the action of light produces or changes the magnitude of an electric current are properly appreciated, they are likely to become very widely employed At least four types of these are now available—the selenium cell and its congeners, the alkali metal cell—operating on the external photoelectric effect, and often called a photoelectric cell to the exclusion of the others—the electrolytic cell, and the dry plate rectifier cell Of these, the electrolytic cell, in which the electromotive force is changed when the electrodes are exposed to light, is as yet little understood, although it is likely to be of value for some purposes More attention is being paid to the rectifier cell, which is the development of a crystal rectifier which has been found recently to be sensitive to light and is going to be very important Selenium cells employ a half

conductor of a similar type to the crystal, but work simply by its change in resistance when illuminated, Ohm's law being obeyed, which is not true of rectifiers

Choice of cell for any particular purpose depends upon exactly what is required of it, but the answer that an engineer wants in most of the less complicated industrial applications can be illustrated by performing an experiment, in which the current through an incandescent lamp is altered until it produces a current of a few microamperes in the circuits of various cells exposed to its light Selenium cells are found in this way to be the most sensitive, then electrolytic cells, gas-filled alkali cells, and rectifier cells, and the vacuum alkali cells come last On the other hand, vacuum alkali cells give a response proportional to the intensity of the light, provided its colour is not altered, and have the great advantage of having an effectively instantaneous response, whereas the response of the selenium cells bears a less simple relation to the intensity of the light and may not reach a

\* Substance of a lecture-demonstration given by Mr C C Paterson on Jan 5 at the Physical and Optical Societies' Annual Exhibition of Scientific Instruments and Apparatus at the Imperial College of Science, South Kensington

steady state for several seconds. Again, the selenium cell is most sensitive to red light and the potassium vacuum cell to green light, although to a green which is well to the short wave-length side of the region of maximum visual acuity. With a vacuum cell in which the sensitive cathode is a very thin film of caesium on a base of caesium oxide the maximum is in the infra-red. No one of these cells agrees with the eye about colour in giving a maximum in the yellow which appears brightest to the eye.

The different sensitivity of different alkali cells to light of different colours is applied in modern lamp photometry to determine accurately whether the light from two incandescent lamps is of the same colour, and therefore whether the two filaments are at the same temperature, on the principle that if two cells of different colour sensitivity are adjusted to give the same current when exposed to light of some definite colour, they will give the same current when similarly exposed to light of the same colour even if its intensity is different, but will not give the same current if the colour is different.

Amongst the laboratory uses of photoelectric cells may be mentioned the demonstration by one of the modern forms, that photoelectric emission is independent of temperature whereas thermionic emission is not. This has already been accomplished in several ways, but can be shown rather prettily with a caesium cell, which has a readily measured thermionic current below 200° C. One of these cells is mounted in a small oven and the thermionic current from it (if any) found by the ordinary direct method, whilst light which produces a photoelectric current too small to deflect the thermionic galvanometer is allowed to fall on the cell simultaneously and is rendered intermittent by passing it through a rotating disc. The photoelectric current through the cell is then also intermittent and may be amplified independently of the thermionic current and fed to a loud speaker, the sound from which is a measure of its magnitude. When the cell is cold there is a photoelectric current but no thermionic emission, but, when the oven is heated, a thermionic current develops rapidly, whilst the sound from the loud speaker, and hence the photoelectric current, is not appreciably changed.

### Physiological Basis of Sensation.

IF we are to regard a sensation as a change in consciousness in response to a stimulus applied to a sense-organ, then the sensation evoked by a given stimulus will depend on the complexity of the consciousness of the particular individual. This will vary enormously from person to person, depending on heredity, education, experience, and so on and will differ enormously in man and in animal. This variation, however, is no justification for the abandonment of investigation, but is rather a guide to the choice of the most elementary species and the most fundamental processes for experiment.

Prof E D Adrian, for the purposes of the discussion which he opened on Sept 24 in Section I (Physiology) of the British Association, presented the view that the structural organs involved—namely, the sense-organs, sensory nerve-fibres, and the collection of nerve cells with their interlacing fibres in the brain—work in a fairly simple way. At any rate, the messages or nerve impulses which pass from the sense-organs are fairly simple, each consists of a very brief wave of activity—in the larger fibres each point remains in the active state for only a few thousandths of a second and the wave travels at a speed of 30 metres a second or more. The passage of an impulse involves a very small expenditure of energy, but fortunately some

of it can be easily detected, for it appears as an electric current flowing between the active and inactive parts.

By amplifying these electric changes, Adrian has been able to record the passage of impulses in each nerve-fibre, and has found that a succession of impulses passes up to the brain whenever a sense-organ comes into action. An active sensory ending usually discharges a rhythmical series of impulses with a frequency in the neighbourhood of 20-100 a second, and the sense-organ, like the nerve-fibre, behaves with machine-like regularity, giving always the same discharge of impulses for the same stimulus provided that other conditions are unaltered.

Adrian has recorded similar electrical changes in the optic nerve, which developmentally is a part of the brain, and there is no reason to suppose that changes do not occur in the brain itself similar to those in the sense-organs and their nerve-fibres.

Prof Frank Allen, of the University of Manitoba, brought forward evidence of a quantitative character in support of the elementary and fundamental physiological basis of sensation. The same law is found to connect the magnitude of the response elicited by a definite adequate stimulus of a sensory organ irrespective of what the sensory organ may be.

Sir John Parsons also contributed to the discussion, pointing out, among other things, the valuable data derived from clinical examination of patients afflicted with such partial deficiencies as colour-blindness.

### University and Educational Intelligence

CAMBRIDGE—Candidates for the recently established Goldsmiths professorship of metallurgy are requested to communicate with the vice-chancellor on or before Jan 16. The salary attached to the chair is £1200 per annum.

The Raymond Horton-Smith prize for the present session has been awarded to Dr W D Newcomb for his thesis on the relationship between peptic ulceration and gastric ulceration and gastric carcinoma.

LONDON—Mr O L V de Wesselow has been appointed as from Dec 1, 1931, to the University chair of medicine tenable at St Thomas's Hospital Medical School. Since 1920 he has been chemical pathologist to St Thomas's Hospital.

ST ANDREWS—The last examination for the diploma of L L A has been held, and the scheme has now been wound up. Begun in 1877, when there was no opportunity for women to enter the universities and when the L L A examination afforded them an opportunity of obtaining a diploma attesting their attainments in literature, science, and philosophy, the scheme grew gradually up to the year 1909, when there were as many as 1090 candidates in one year. By that time the effect of the admission to the universities of women had diminished to some extent the usefulness of the examination and the numbers gradually decreased. During its existence the L L A has attracted 36,017 candidates and 5119 diplomas have been conferred.

THE sixth World Conference of the New Education Fellowship will be held at Nice on July 29-Aug. 12, under the presidency of Prof P Langevin, professor of experimental physics in the École Normale Supérieure, Paris. The theme for the Conference is "Education and Changing Society." Main lectures on the general theme have been arranged, also sectional lectures on special subjects and on progress within national systems of education, and study courses. Further information can be obtained from the Conference Secretary, New Education Fellowship, 11 Tavistock Square, London, W C 1.

## Calendar of Geographical Exploration.

Jan 10, 1811 —The Rocky Mountains

David Thompson discovered the Athabaska Pass, along the main route over the Rockies to Columbia. Thompson was one of the greatest land explorers, covering at least 50,000 miles of mainly unknown country and recording his surveys accurately and fully. For twenty-seven years he made innumerable astronomical observations on long journeys. The result was a survey of south-western Canada from Lake Superior to the mouth of the Columbia river, making possible the accurate mapping of its mountains, rivers, and lakes. Regions of the 'muskrat' country, north-east of Cumberland House, have never been visited since his time. Later, Thompson worked on the boundary survey after the Anglo-American war. Recognition of the importance of his work was tardy, for poverty prevented him from publishing either a map of his explorations or his "Narrative" or "Journals."

Jan 11, 1930 —The South Arabian Desert

Bertram Thomas set out on his second journey into the Rub'al Khali, when he penetrated almost to the centre of that arid waste. His journeys covered ground practically unvisited previously by any European, though Wellstedt, from the crest of Jebel Akhdar in 1836, had seen the great desert in the distance. Much new scientific information is now available about the region, including the first account of its drainage system.

Jan 12, 1878 —The Heart of Arabia

Wilfrid Scawen Blunt and his wife left Meskakeh to cross the Nafud desert southwards to Jabal Shammar. The poet and his wife, who was a granddaughter of Byron, had developed a romantic sympathy with bedouin society, and had been initiated into desert life among the Anaze and Shammar tribesmen of the Hamad and the Mesopotamian steppes. Blunt journeyed to Jaufr in quest of a bride for his 'blood-brother', a young Arab of the Palmyrene oasis. Thence he and Lady Anne decided to visit the Emir of the Shammar as European guests. Their achievement in travelling openly, with a woman in the party, through the strongholds of Arabian fanaticism is remarkable. Their records proved of the utmost value for the geography of this little-known region.

Jan 13, 1772 —Marion and Crozet Islands

N T Marion du Fresne discovered the islands now bearing the above names. Bougainville, on his voyage round the world, 1767-69, had brought back with him a native of Tahiti as a 'human curiosity'. The French Government wished to return the native to his home. Marion volunteered to take him to Tahiti, and sailed from Île de France (Mauritius) in October 1771 with two vessels. The unfortunate native contracted small-pox and died while the ships were anchored off Madagascar. Marion thereupon decided to go southwards to search for the antarctic continent. He named the island which he discovered on Jan 13, Terre de Espérance, because it gave him the hope that he was near the southern continent. The islands are bare and rocky, but the weather was foggy, and a multitude of white spots led the discoverers to think that there were flocks of sheep upon them. The *Challenger* expedition, 1872-76, explored the islands and found these spots to be moss patches. Marion's expedition went on to New Holland (Australia) and New Zealand. It made a stay of some duration in the latter, but Marion was murdered by the natives, and his lieutenant, Crozet, brought the vessels home.

The account of the voyage, with its full descriptions of Maori life, was compiled from Crozet's log.

Jan 14, 1699 —Australia and the East Indies

William Dampier sailed from the Downs on H M S *Roebeck*, one of the earliest government expeditions sent out from Great Britain purely for discovery. Dampier's account of his former voyage in the *Cygnnet*, when he had observed the shores and natives of New Holland (Australia), had roused the interest of the Earl of Pembroke, then Lord High Admiral, and Dampier was commissioned to explore the southern seas. He anchored in Shark's Bay, on the western coast of Australia, on July 7, 1699, and thence surveyed the coast for 900 miles. Leaving Australia, he discovered Dampier Strait, between New Guinea and Waigiou. He also proved that New Britain is an island separate from New Guinea, and surveyed much of its coast.

Jan 16, 1772 —Kerguelen Island.

Yves Joseph de Kerguelen-Trémarec, a Breton noble, sailed from the Île de France (Mauritius) commissioned by the French Government to search for "a very large continent to the south of the islands of St Paul and Amsterdam", a land on which the Sieur de Gonneville was supposed to have stayed in 1504. He found a land which he named South France. He thought it formed the central mass of the antarctic continent, and held out high hopes of its commercial importance. But on a second expedition in 1773 he discovered it to be bleak and barren, and Cook had in the meantime sailed far to the south of it in open seas, so that Kerguelen now knew it to be an island. He renamed it the Land of Desolation. It is to-day called Kerguelen Island in honour of its discoverer, and has from time to time been used as a base for valuable scientific observations.

## Societies and Academies.

### LONDON

Royal Meteorological Society, Dec 16 —W C Kaye and C S Durst. Some examples of the development of depressions which affect the Atlantic. Three typical cases show examples of (1) a polar depression being intensified by the introduction of warm air from the Gulf of Mexico, (2) the formation of a family of depressions between Pacific maritime polar air and warm Gulf air, (3) the formation of depressions on a quasi-stationary front. A majority of the families of depressions which cross the Atlantic originate in one or other of these ways —Alfred A Barnes. (1) Rain-gaugings near Belper and Duffield, Derbyshire. A complete analysis of the yearly readings taken at 19 rain-gauges at the southern end of the Pennine Chain during a period of 66 years from 1865 to 1930 inclusive —(2) Rainfall reviewed a common long-average period for each country of the British Isles. A new survey during a period of 68 years from 1863 to 1930 inclusive —W H Pick. Visibility with saturated air. The horizontal visibilities at Worthy Down and Felixstowe, over a period of four years, whenever the air was saturated are examined. All degrees of visibility (except the very best) were well represented. A large percentage of the cases of saturated air were unaccompanied by either fog or mist. The effect of wind force upon the visibility accompanying saturated air is also examined.

### PARIS

Academy of Sciences, Nov 30 —G Bigourdan. An influence of the moon —Lucien Cuénot was elected a non-resident member in succession to the late Eugène

Cosserat—A Marchaud Correction of an earlier communication—Alexandre Wundheiler Conditions for an inextensible flexible surface—Georges Bouligand A new extension of a theorem of Émile Picard—Mandelbrojt The generalisation of a theorem on holomorphic functions in a demi-plane—W K Turkin A generalisation of the theorem of Frobenius—Georges Ranque and Pierre Henry The determination of the characteristics of the viscous elongation of hot metals A modification of Kohn's method, in which the reversible extensions of the test-piece are utilised to regulate the temperature, the extension remaining constant The decreasing temperatures under constant load can be expressed as a linear function of the logarithm of the time—Émile Sevin Concerning binary systems—A Guillet Application of the deviation method and the zero method to the electromagnetic measurement of small deformations—M Pauthenier and Mme Moreau-Hanot The adsorption of ions by spherical conducting particles in an ionised field—Ch Sadron Ferromagnetic moments and the periodic system From the experiments described the author concludes that the atomic moments, in Weiss magnetons, of elements in the same column of the periodic table are identical—Antonie Rostagni Oscillations maintained by valves with positive grid—A Kastler The circular polarisation of the Raman radiation—A Cotton Remarks on the preceding communication A preliminary account of the action of a magnetic field of 46,300 gauss on the Raman lines—J P Mathieu The influence of the nature of the chemical linkages on the production of circular dichroism A solution of chromium hydroxide dissolved in tartaric acid contains a normally ionised salt it slowly changes into a complex salt from which ammonia fails to precipitate chromium hydroxide Facts are given which render very probable the hypothesis that the circular dichroism is proportional to the concentration of the complex compound formed in the reaction—Henri Muraour and G Aunis The variation of  $\rho d\epsilon$  with the density of charge for a vaseline powder  $B$  and a centralite powder  $B$  The phenomenon previously described for nitroglycerine powders is repeated with nitrocellulose powders—Guichard, Clausmann, Billon, and Lanthony The experimental method suitable for establishing the independence of the amount of hydrogen present and the hardness of electrolytic iron Reply to a criticism by Guillet, Roux, and Cournot—G Rumeau The velocity of crystallisation of the different forms of dimethyl tartrate—R Lespieau, M Bourguet, and R Wakemann The Raman effect and chemistry The cyclopropane nucleus The nucleus of a cyclopropane compound is characterised by (1) a very strong line near 1200 corresponding to the C-C linkage, and (2) by two strong lines at 3000 and 3065 corresponding to the C-H linkages The spectrum of the nucleus differs entirely from that of saturated open fatty chains—R Trehin The absorption of aqueous solutions of some chlorides in the ultra-violet Solutions of the chlorides of sodium, potassium, barium, and strontium were studied details of the methods of purification are given Absorption of very dilute solutions of these chlorides is due entirely to the presence of chlorine ions—Jean Cournot Results of corrosion tests on rustless steels—J Bougault and E Cattelain The elimination of the phosphate ion as lead phosphate in the analysis of salts by the wet method—André Meyer and Robert Vittenet The phthalone imides and their derivatives—André Demay The conditions of orogenesis and of Hercynian metamorphism in the southern edge of the Rodez massif—Georges Corroy The variations of facies and thickness of the

Argovian in the eastern border of the Paris basin—E Aubert de La Rue The presence of a Tertiary fossil flora in the Kerguelen Archipelago—R Lambert The tectonic of the western flank of the mountain of Néron, near Grenoble—J Dufay The emission bands of the aurora borealis in the spectrum of the nocturnal sky—Ladislav Gorczynski Maximum of intensity of solar radiation observed at Nice and Thorenc in the Maritime Alps—Octave Mengel The rôle of the condensation of water vapour in supplying springs—Pierre Lesage *Lepidium sativum* at different latitudes—Aug Chevalier The extension and propagation of the rosette disease in *Arachis* in Senegal—R Legroux and Kemal Djemil Lysis of the glanders bacillus and of the pyocyanic bacillus—Jean Regnier and Robert David Contribution to the study of microbial multiplication The influence of the composition of the liquid media usually employed in laboratories on the value of the microbial growth (*Pyocyanic bacillus*) A table showing the comparative results with seven media is given The microbial growth follows practically the same course with all the media—Remlinger, Manouelian, and Bailly Researches on the nerve centres of the tortoise inoculated with the rabies bacillus The virus of rabies, inoculated in the brain of *Testudo mauritanica*, preserves its virulence for at least six months This virulence occurs with the presence of Negri corpuscles and the formations described by Manouéhan and Viala in all forms of rabies No apparent symptom develops in the reptile—C Levaditi and A Vaisman The curative action of liposoluble bismuth in experimental syphilis without external symptoms Liposoluble bismuth (bivatol) exerts a strong and durable curative action on latent syphilis in mice—Ugo Lombroso The inoculation of man with bacterial strains isolated from Tunisian trachomatous subjects

## ROME

Royal National Academy of the Lincei, June 5—F Severi General resolution of Dirichlet's problem for biharmonic functions—C Somigliana Variability of mass A system of dynamics is deduced which preserves the general lineaments of classical dynamics without prescribing *a priori* a definite form of dependence of the mass on the velocity—L Cambi and A Cagnasso Dithiocarbamates and nitrosodithiocarbamates of iron—E Bompiani Integral surfaces of two or more equations with partial derivatives of the third order—Ugo Broggi A problem of interpolation—L Labocchetta The fundamental forms of discontinuous constants as circular functions—T Viola The dextro derivative of a function continuous towards the right and derivable towards the right—Miron Nicolesco An equation with partial derivatives characterising the means of Picone—Pia Nalli Rigid transports and relativity—G Sansone The partial convergence of the developments in series of orthogonal functions Extension of Kolmogoroff's theorem to developments in Fourier's series—G Mammanna The product of series capable of summation by Cesaro's method (2)—G Krall A complement to the theory of adiabatic invariants according to T. Levi-Civita—G Lampariello Propagation of waves in isotropic, but not necessarily homogeneous, elastic media—G Galanti Algorithms of motorial calculus—A Consiglio Power of a translatory-circulatory current in presence of a Joukowski obstacle An earlier communication (1930) has given an evaluation of the resultant of the dynamic actions of an irrotational, permanent, translatory-circulatory current on a Joukowski pisciform obstacle The power relative to such a current is now calculated—B Caldonazzo Vortex in a field limited by a cardioid.

In general, the presence of salient cusps on rigid walls bathed by a perfect liquid in plane motion contributes to the dynamic actions exerted on the walls themselves. The case here considered is the motion caused by a free, isolated vortex in the field limited by a cardioid, which exhibits a cuspid salient with respect to the field of motion—G Cecchini. The absolute magnitude of the Cepheids. Although difficult to treat, parallactic data obtained by direct observation are able to confirm, by way of laws valid for ordinary stars, the necessity of a systematic correction in the absolute magnitude of the Cepheids determined from the period-luminosity curve. The correction found for the zero point is in the sense and of the order established by various means by several investigators and indicates that the distance of every celestial object deduced on the basis of Shapley's curve should be reduced by the factor 0.6—M Tenani. Contribution to the knowledge of the tides of the Arctic Ocean. Consideration of the data, collected during the sojourn of the *Città di Milano* at Spitsbergen in June-July 1928, furnishes fresh confirmation of the view, expressed by Nansen and supported by others, that the Arctic Ocean is continuous. It is not in accord with Harris's hypothesis of the existence of a wide expanse of unknown land in the zone still unexplored—G A Barbieri. Compounds of bivalent and of trivalent silver. Argentopyridine persulphate, in which the silver functions as a bivalent metal, forms mixed crystals with the analogous cadmiopyridine persulphate, and argentiphenanthroline persulphate with cadmiophenanthroline persulphate. When hydrolysed, both the so-called silver peroxodinitrate,  $\text{Ag}_2\text{NO}_{11}$ , obtained by electrolysis of concentrated nitric acid solution, and a nitric acid solution of the oxide  $\text{Ag}_2\text{O}$  yield the oxide  $\text{Ag}_2\text{O}_3$ , for which the equivalent ratio between active oxygen and silver has the value 1.51—L Mascarelli and D Gatti. Contribution to the knowledge of diphenyl and its derivatives (8). New 2'-disubstituted derivatives of diphenyl. The compounds described are the nitrochloro, nitrobromo, nitroiodo, nitrohydroxy, aminochloro, aminobromo, aminoiodo, chloroiodo, chlorobromo, and iodobromo derivatives. The scheme was as follows:  $\text{NO}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2 \rightarrow \text{NH}_2 \cdot \text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2 \rightarrow \text{X} \cdot \text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4 \cdot \text{NO}_2 \rightarrow \text{X} \cdot \text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4 \cdot \text{NH}_2 \rightarrow \text{X} \cdot \text{C}_6\text{H}_4 \cdot \text{C}_6\text{H}_4 \cdot \text{X}$ , where X represents a halogen atom—G Tallarico. Preservation and productivity of corn grain. Functional predetermination. In order to maintain the activity of the embryo of seed wheat during storage, the conditions must be such that the consumption of the reserve food material, to be utilised by the young plant, is reduced to a minimum and that the lethargic rest of the embryo is not disturbed. This is attained by limiting the respiratory activity to the minimum required to keep the seed in a living condition. The seed should, therefore, be dried and stored in a cool place, and accumulation of carbon dioxide in the mass should be permitted. Experiment shows (1) that grain from the interior of an undisturbed heap gives higher yields of both grain and straw than that from the surface layers of the same heap, and (2) that grain left at rest furnishes higher yields than the same seed subjected to turning during storage.

#### SYDNEY

Linnean Society of New South Wales, Sept. 30.—H L Jensen. Contributions to our knowledge of the Actinomycetales (2). The definition and subdivision of the genus *Actinomyces*, with a preliminary account of Australian soil Actinomycetes. These organisms can be divided into two main groups (1) *Actinomyces*, which produce an aerial mycelium with spores. These

are the common soil inhabitants (ii) A new genus in which spores are not produced in the aerial mycelium, and there is a tendency to assume a bacterium-like appearance. These are more rare soil forms, but include many parasitic forms—A Jefferis Turner. Revision of Australian Lepidoptera—Supplementary Corrections and additions to families previously revised, and descriptions of four genera and thirty-nine species as new—R J Tillyard. The wing-venation of the order Isoptera (1). Introduction and the family Mastotermitidae. This paper deals with the wing-venation of the archaic Australian termite *Mastotermes darwiniensis* Frogg. The determination of the homologues of the veins by this method shows some interesting results, the most important being the delimitation of the anal lobe of the hindwing, which is now proved not to be homologous with the anal fan of the Orthoptera, but is rather comparable with the alula of the Diptera. An interesting discovery was made in the form of a hitherto unrecorded small wing-flap attached to the clavus of the forewing and folding beneath it, this closely resembles the structure called the alula in the coleopterous family Hydrophilidae. It appears to be a reduced homologue of the anal lobe of the hindwing.

#### WASHINGTON, D C

National Academy of Sciences (*Proc.*, Vol. 17, No. 9, Sept. 15).—Emma L Fisk. The chromosomes of *Lathyrus tuberosus*. The haploid number is seven, as in other species of *Lathyrus*. The chromosomes are unusually large and varied sizes and shapes—Th Dobzhansky and Jack Schultz. Evidence for multiple sex factors in the X-chromosome of *Drosophila melanogaster*.—John W Gowen. Body pattern as related to mammary gland secretion. Analysing the data from about 6000 Jersey cows, it is shown that weight and a wedge-shaped form when viewed from in front are indicative of milk yield. Other dairyman's 'points' are without significance. All correlations of dimensions of an animal and milk yield are materially influenced by the cow's age, and for the purpose of this paper, the data were adjusted to the age of 8 years 3 months—F Zwicky. Why crystals exist. Ordinary cohesive forces with action radii of the order of atomic dimensions are responsible for condensed states of matter but are not characteristic for the crystalline state. The transition from liquid to crystal is sharp and can only be effected by the simultaneous co-operation of large numbers of atoms in a directional arrangement, this co-operation will not generally have the same symmetry character as the primary structure of the crystal. Hence crystals are supposed to have a primary structure, revealed by X-ray analysis, on which is superimposed a secondary structure, the former is characterised by structure insensitive properties, the latter by structure sensitive properties—Paul S Epstein. On the air resistance of projectiles. A theoretical discussion. Solutions are derived of Euler's equations of hydrodynamics for velocities greater than that of sound for the two-dimensional case of polygonal contours. At very high velocities the expressions are valid for contours with curved sides and for three-dimensional bodies—T L Ho. High vacuum pressure control apparatus. A hot wire or ionisation gauge is attached to the vacuum system to be kept at constant pressure. This gauge is connected with a galvanometer which controls a vacuum tube amplifier, the latter in turn controls magnetically an iron float in a U-tube of mercury, so arranged that it opens or closes a connexion between the vacuum system and a vacuum reservoir attached to a pumping system.

## Forthcoming Events.

## Societies

## FRIDAY, JANUARY 8

- ROYAL GEOGRAPHICAL SOCIETY, at 3 30—Mrs Murray Chapman Through Lapland in Winter with Sledge and Reindeer (Christmas Lecture for Young People)  
 INSTITUTION OF MECHANICAL ENGINEERS, at 6—S B Freeman Modern Types of Propelling Machinery for Mercantile Marine Use (Thomas Lowe Gray Lecture)  
 GEOLOGISTS' ASSOCIATION (at University College), at 7 30—Dr W F Whittard An Expedition to East Greenland, 1929 (Lecture)

## SATURDAY, JANUARY 9

- ROYAL INSTITUTION OF GREAT BRITAIN, at 3—Sir William Bragg The Universe of Light (Christmas Lectures) (6)  
 Light from the Sun and the Stars

## TUESDAY, JANUARY 12

- PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, at 8 30—W Deacon The Romance of Perfumes (Lecture)

## WEDNESDAY, JANUARY 13

- ROYAL SOCIETY OF ARTS, at 3—Prof E N da Costa Andrade The Vacuum, or the Importance of Nothing at All (Dr Mann Juvenile Lectures) (2)

## THURSDAY, JANUARY 14

- ROYAL GEOGRAPHICAL SOCIETY, at 4—Revision of Bye-Laws—At 5—Geographical Film  
 LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5—Discussion on Generalisations of Fourier's Integral  
 INSTITUTION OF CIVIL ENGINEERS (Birmingham and District Association) (at Chamber of Commerce, Birmingham), at 6—N G Gedye The Mechanical Handling of Coal at Ports (Vernon Harcourt Lecture)

## FRIDAY, JANUARY 15

- SOCIETY OF CHEMICAL INDUSTRY (South Wales Section) (jointly with Institute of Chemistry—South Wales Section) (at National Oil Refineries, Skewen), at 7—Dr A E Dunstan Liquid Fuels To-day and To-morrow (Lecture)

## Public Lectures

## FRIDAY, JANUARY 8

- IMPERIAL COLLEGE OF SCIENCE (Royal College of Science), at 5 30—Dr T M Finlay The Evolution of Landscape Vulcanism (Swiney Lectures) (2)

## MONDAY, JANUARY 11

## Knowledge and Social Service.

IT may appear otiose to compare the South African War with the Great War. But one curious difference *saute aux yeux*. At the conclusion of the South African War, there was fierce denunciation of our Army, of our aristocracy, of our neglect of science. The attempt was even made to reform the War Office! Prof H E Armstrong, now a Nestor both among men of science and among educationists, was outspoken on the neglect of science in our schools. To him was largely due the creation of the Educational Science Section of the British Association in 1901, at the first meeting of which he urged the scientific treatment of education in all its branches, and the introduction of scientific conceptions into every sphere. He is, however, still far from satisfied with the scope and method of scientific teaching in our schools, and our columns from time to time afford evidence that he has not reached the end of his long, long trail winding towards a perfectly organised nation.

Norman Lockyer, exemplar of that race of pioneers who "debouch upon a newer, mightier world", founded the British Science Guild in 1905 with the object of promoting the application of scientific methods and results to social problems and public affairs. He urged with success upon the Government the need for more liberal support of university education and scientific research. Haldane, with prevision of the life-and-death struggle facing the nation, worked out a scheme for the development of technological study and research at South Kensington, significantly called the London Charlottenburg scheme. The University of London, under the brilliant guidance of Sir Arthur Rucker, endeavoured to set its house in order. The University of Birmingham, our first civic university, founded in 1900, was the prototype of a powerful group of modern universities. The Government, ceasing to dally with the question of educational reform in its broader aspects, accepted with a single gesture Robert Lowe's advice to "educate your masters" and Matthew Arnold's advice to "organise your secondary education."

"Bliss was it in that dawn to be alive,  
But to be young was very Heaven!"

Contrast the vigour of those pregnant years, especially the earlier years after the South African War, with the temperament of the public since 1918. The Great War summoned the whole nation to arms. Silent and abashed we stand before the Cenotaph, asking whether any sins of

commission or omission on our part have contributed to the loss of our friends, to the cataclysm which has overtaken the world. Armistice Day is celebrated with increasing solemnity year by year. We have the feeling that the childish question, "What did you do, daddy, in the Great War?" is an indictment rather than an ingenuous request for information. We cannot school ourselves to learn the stupendous lessons of the War. Like that adorable dreamer, we cherish lost causes and forsaken beliefs, unpopular names and impossible loyalties. The 'schoolmen' attempt again to spellbind us with their words. The War Office 'carries on'.

That mental attitude has continued ominously for thirteen years. But the shattering events of the last few months have awakened the nation to a more realistic frame of mind. Especially significant, we would suggest, is that university professors have been stimulated to express their opinions more freely, to give a lead to an inarticulate but well-disposed public, reviving a sound tradition established by men like Playfair, Huxley, Norman Lockyer, Roscoe, and other men of science who could be named. Two recent pronouncements of this *genre* deserve special mention.

Prof Ruggles Gates, professor of botany and plant biology in the University of London, addressing the Educational Science Section of the British Association on "Eugenics in Education", at the recent centenary meeting, said that the elements of our community most capable of producing men of achievement, intellectually, socially, or financially, are failing to reproduce themselves, and are being eliminated "unobtrusively but fatally". Parliament, he declared, is almost wholly lacking in the type of intellect capable of restoring the nation to biological soundness by legislation. "One must conclude that almost every important legislative measure since the War, when our racial and economic resources were so greatly in need of conservation, has been effective rather in hastening racial degeneration by its disregard of the fundamental facts of biological inheritance." Prof Gates pleaded not for more education but for better education, especially in those biological principles which underlie national progress. Following that would come leadership on questions of population, marriage selection, the production of children, racial crossing, and related matters.

The other pronouncement was even more outspoken and relevant to our immediate difficulties. Prof John Hilton, the first Montague Burton

professor of industrial relations at the University of Cambridge, referred in his inaugural lecture to the depressed condition of industry. The cost of living has fallen but wages and interest have held, hence unemployment. Industry will have to live on its own fat, which is already very lean, and nobody will feed it with the capital which comes from savings. There is no formula to settle wages in this or that industry, to adjust the claims of worker, investor, and public—only a code of rules which each of the contestants ought to observe. For many years industry has been baffled and spellbound by forces not its own. Take the curse from industry and it will give the world good service.

Whatever adjustments are required to ensure progressive social service should be based upon the best knowledge available. Without, therefore, expressing approval or disapproval of the professorial pronouncements referred to, we welcome their appearance as a sign of new life. "The War and the Russian Revolution", says Bertrand Russell, "have made all timid men conservative, and professors are usually temperamentally timid", and Hogben refers to "the intellectual discouragement which is the heritage of a World War". Timidity and intellectual discouragement have only complicated our problems since the War! How long must a distracted world wait before its wise men shall be able to sound again a note of encouragement?

"For, lo, the winter is past, the rain is over and gone, the flowers appear on the earth, the time of the singing of birds is come, and the voice of the turtle is heard in our land"—*The Song of Solomon*  
T. L. H.

### An Odyssey of Science.

*Past Years an Autobiography* By Sir Oliver Lodge. Pp 364 + 13 plates (London: Hodder and Stoughton, Ltd., 1931) 20s net.

IT can confidently be said that the life-story of no man in the scientific world to-day, is likely to be of greater interest to us than that of Sir Oliver Lodge. There is more than one reason for this, but the one above all others which we would have Sir Oliver realise, is that he has gained a quite peculiar place in the regard of his fellow-countrymen. His eminence in science is known to the multitude, and there is no one who has shown greater gifts in teaching them about the things in science on which they particularly want more light. It may be quite true that it is Sir Oliver's concern with matters

'psychic' which has aroused the widest interest of all, and will, perhaps, secure him most readers. But those in science whose memories go back to his early days, will say that they saw him then clearly predestined to fame as a scientific discoverer and as a leading expositor of scientific thought to his generation.

On Sir Oliver's position within the scientific world it is, of course, unnecessary to enlarge here, and, fortunately for the writer of this notice, there appeared recently in these columns (Dec 12, p 982) an appreciation of his chief work in the advancement of science, contributed by a more authentic hand—"R. T. G." Readers of *NATURE* will all feel that for longer or shorter years they have not only learned from him, but have also lived, as it were, in his genial company. Different readers will want to know different things in particular about his life, and so far as one can judge, none will fail to find them in this book.

The difficulty of writing the book must have been very great, even to such a practised hand. The wealth of material alone was calculated to create dismay, but most impressive of all is the evidence the book gives of the difficulties confronting an honest man, when he tries to make sure of recollections of his own life. In the narrative of ordinary events, this may not matter very much, but when a man is to record the course of his thought, the exact sequence of events, and his particular share in discovering, it is very different. The discoveries in which Sir Oliver shared have been of the kind round which the historians of science gather in subsequent generations, with unceasing curiosity and ever sharper scrutiny. At least three accomplished chemists are busy to-day still auditing the intellectual accounts of Priestley and Lavoisier. Happily, in the scientific world, the private 'exchange of ideas' is widely prevalent, both nationally and internationally. But here, though without evil intent, exchange may often be robbery. We continually witness men having their own ideas, like their own jests, presented to them as fresh-minted from another mind. Nowhere does Sir Oliver show his qualities more arrestingly than in dealing with this difficulty in relation to his greatest scientific discovery. He does not balk the reader of the pleasure of listening to first-hand personal memories, the incidence of ideas, the plans of campaign, the talks with friends, the obstacles to progress, the 'ifs' and 'might have dones'. No one knows better than he how to keep human. But when we come to the question, so often asked of his scientific

friends, "What part exactly did Sir Oliver Lodge take in the discovery of electro-magnetic radiation?" he provides us with a reply by reprinting words used by the president of the Royal Society in 1899, beginning "The Rumford medal is given to Prof Oliver J. Lodge in recognition of his researches on radiation and on the relations between matter and ether."

Space can suffice for little more than a general indication of the course which Sir Oliver has taken in his book. The tale extends from very early days, where it is relatively full, through middle life, where there is necessarily great compression, finally to the present day, where we should have to regret much left unsaid, if it were not already within our memories. Here, as in other ways, Sir Oliver shows a talent for omission; he has spared the reader minute reference to 'sources', lists of books and papers, and vexatious footnotes; he has scarcely drawn at all upon what must be a prodigious store of correspondence. Those who have lived longest beside Sir Oliver, and some of those on close terms of friendship, will find much new to them, and of exceeding interest, especially about his earliest days. The younger men will find here a graphic story of the state of physical science before the days of the 'Revolution'. They will see where thought was, who and what men were in the expectant world of science. Speaking in 1889 he said, "the long line of isolated ripples of past discovery seem blending into a mighty wave, on the crest of which one begins to discern some oncoming magnificent generalisation. The suspense is becoming feverish, at times almost painful." On the great questions of to-day, physical and philosophical, Sir Oliver gives in compact and clear terms his present opinions, and they are likely to carry comfort to some who are in sore perplexity.

At the outset of Sir Oliver's story, we learn some interesting facts of genealogy, such as that his paternal grandfather, who was in Anglican orders and also a schoolmaster, brought in an Irish strain, that his father, originally intended for medicine, went from the paternal home in Essex to settle amid the Five Towns, where at Penkull, near Stoke, this, the first of seven sons, was born. To a wonderful mother, the son ascribes, besides much else, the intellectual inheritance of himself and his distinguished brothers Richard and Alfred.

No part of the story of his life is likely more to touch the heart of readers than that dealing with Oliver Lodge's schooldays. It tells of a child, with exceptional appetite and aptitude for learning, in the

hands mainly of bad teachers of mainly uncongenial subjects. That was, no doubt, the common case then, but the accompanying cruelty to body and spirit was such as to make Sir Oliver say now "My schooldays were undoubtedly the most miserable part of my life." But here, as elsewhere, the victim says what he can for those who have despitefully used him, and he seeks out good in all the uses of adversity.

Schooldays were ended at fourteen by an exacting father, who for the next seven years set himself inflexibly to immerse and retain his eldest son in his business. This business was a prosperous agency for the supply of blue-clay and other requisites to the potters. It involved not only keeping the books but also continual travel within and beyond the Potteries. The story of these hard years of school and business is shot with many gleams of sunshine. We see the first lure of science, the earliest efforts, almost clandestine, at experiment. Then emancipation begins through the strong and benign influence of his mother's sister, Miss Heath ("Aunt Anne"), who lived in Fitzroy Square, London, and had been the first to feed her nephew's appetite for science. She comes into the story like a good fairy. During a winter with her, he attended classes and lectures, Tyndall became his hero, and from the Royal Institution he "walked home, as if on air." After his return from this to servitude we read of rapid developments, among other things, preparation for London matriculation (1871).

During two successive years, Lodge spent a period at the Royal College of Science, London, attending the special courses for science teachers. Then comes the final determination to break away, which, after his failure to attain the desired haven of Cambridge, brought him to University College, London. There, besides the great mathematical teachers, Clifford and Henrici, the young man found a friend indeed in Carey Foster. With £50 a year, assigned to him by Foster for assistance in teaching work, living as a "rebel from home" a life of real privation for three years in Camden Town lodgings, Oliver Lodge then set himself at last fairly on the highway along which he was to travel thenceforth. He became assistant professor of physics at University College. Then, too, began the splendid companionship that brings much radiance into this story of past years. Lodge left London in 1881 to become the first professor of physics at University College, Liverpool. In 1900, under the influence of Joseph Chamberlain, he was made the first Principal of the new University at Birmingham, remaining there until he resigned

in 1919 and went to live near Salisbury. Such, in bald outline, was the course of events. They are not dealt with consecutively in the book, and the whole shaping and chaptering of it may not please literary formalists, but somehow it all seems just right for the purpose.

Sir Oliver has shown, to an extent that few could safely attempt, how he has played the great game of life. The frank record of his difficulties and doubts, his strivings and disappointments, his ambitions and defeats, will not only strike many responsive chords in the minds and hearts of the elders, but also will afford invaluable aid to younger men. They will see clearly depicted many difficulties that are among the hardest not only in the art of scientific discovery, but in life itself. They will see how at times crises arise, fate—and conscience, too—seeming to point with equal fixity both right and left. Those who study education will find here a rich mine. Sir Oliver does not descant much upon the teacher's art, but he exhibited it to a supreme degree in his "first and only text-book", that on "Mechanics", written in 1897, before his first appointment in the teaching world, in his "Easy Mathematics" (1906), and in every effort he has made through life to instruct his fellows. In these columns and elsewhere he has laid us under a heavy debt by his lucid exposition of the revolutionary modern discoveries in physical science. In particular he has been solicitous that the world should appreciate the great conquests that have been in progress at Cambridge during the last forty years.

It is hopeless to enumerate the scientific and human topics on which the book touches, for Sir Oliver looks back on so many "crowded hours of glorious life." The versatility of his interests has been so great that he is not free from the misgiving that he might have done better had it been less. The first occasion on which the present writer met Sir Oliver was when he was expounding an ingenious graphical symbolism for organic chemistry, and certainly the chemists have always felt him to be a very near relation. He had the companionship of philosophers, including an intimate friendship with Arthur Balfour. He has, indeed, moved among all sorts and conditions of men, and browsed in many pastures.

There is one matter of which mention must not be omitted. On all grounds, public and personal, Sir Oliver had warrant for allotting a relatively large share of pages to the history of his experiences, and a recapitulation of his faith, in matters 'psychic'. From the days at University College

in London, when he made the acquaintance of Edmund Gurney, through his experiences at Liverpool, Birmingham, Cambridge, in the island home of Richet, up to the present day the tale is told. It is told, as all else in the book is told, with exactly the same candour and the same control. We can confidently say that it provides just the authentic summary that so many men of science have wanted. More than that there can be no need to say in this notice.

On his way through life, Sir Oliver Lodge has enriched the world with many books. Greatly as these books have been, and are, prized, no one will be more ready than their author to say they will not all endure. Of one, "Modern Views of Electricity" (1889), it has already to be said that after a long and most useful day it has, in one sense, ceased to be. "The discovery of the discontinuous nature of electricity", Sir Oliver says, "caused the book to go out of print." But of this autobiography we shall surely say that no end can be foreseen to its acceptability and service in future generations. It is written by one who is veritably a giant in these days, a man of wonderful endowments and influence. He has participated in revolutionary discoveries in science, and has been a leader in perhaps the most fateful movement of his time—that which is at last making our race conscious of the mighty part that science must henceforth play in human thought and action. He has written of his past years in the spirit of one who wishes to bequeath what he can of the wealth of his experience and his stores of wisdom, and so has produced a human document of rare and abiding interest.

We see in his book some reflection of the nearest intimacies and greatest influences that have affected Sir Oliver's life, above all, those from within his own home. From that we come to understand a little of what has conferred upon this man, who has lived so strenuous a life, the serenity with which he walks among us in these later days, and the sway he exercises upon his fellow-men.

When a man has stepped, however lightly, into his ninth decade, it seems unfair to exact a great deal from him. But many readers of NATURE must have been present during the British Association meeting last September, at the great debate on the recent trend of science, and have heard Sir Oliver sum up, with such sure touch, the performance of each of the protagonists who had been engaged. All who were present will look forward not only with hope, but also with confidence, to further gifts from the man who has already given so much.

ARTHUR SMITHELLS

## Medical Bacteriology

*Medical Research Council. A System of Bacteriology in relation to Medicine. Vol 8. By W. Bulloch, L. Colebrook, J. Cruickshank, R. Cruickshank, A. Dawson, J. T. Edwards, F. Griffith, L. W. Harrison, E. Hindle, Ivy Mackenzie, A. Robertson, R. St John-Brooks. Pp 390. (London: H.M. Stationery Office, 1931.) 21s net.*

CHAPTER I of this volume deals with the Fungi pathogenic to man and is a valuable addition to the ordinary bacteriological literature. We agree with the authors that the space allotted to mycology is so restricted that it is impossible to cover the field even in summary, and we feel that the volume would have been improved if considerably more space had been given to this subject, which is so inadequately dealt with in all medical works. The gain to the book would have been great, and the loss would have been slight if some of the other chapters—for example, those on syphilis and the normal bacterial flora of man—had been even severely cut by the editors in order to give more space to mycology. The authors, however, have made the most of the pages allotted to them, and we congratulate them on a really valuable contribution.

We are glad to see emphasis laid on the fact that growth of these organisms takes place on the common laboratory media, and that, though Sabouraud's medium has advantages, it is not essential in the study of the fungi of ringworm and other conditions.

The chapter on actinomycosis, though short, contains all the essential points, but leaves us still in doubt as to the origin of most of the cases. Bostroem's original view is regarded with grave suspicion, but the alternative hypothesis of alimentary tract infection which the authors favour does not seem to have any more clear proof. The example given of infection round a fragment of a carious tooth found in an actinomycotic lung seems to us to give quite as much support to Bostroem's view as to the other one.

In view of all the work done on the actinobacillus as a causal agent in many of the cases of so-called 'actinomycosis' in cattle, the organism, we think, deserves more attention than has been given to it in the short note by Dr. Griffith, and does demand a revision of the work on actinomycosis.

The short chapter on pathogenic Leptothricæ by Dr. Ivy Mackenzie, giving, with much other information, his well-known observations on the two phases of the meningococcus, is of interest, and though we may not agree with some of his views,

yet the inclusion of this article is thoroughly justified and we think it deserves very careful study

Chaps iv, v, and vi, on the spirochaetes, are excellent. Though the information given in some cases is very limited, yet for a "System" of this kind it is probably ample, and we congratulate the writer on a very valuable article.

Chap vii, on syphilis, is by Col Harrison. This is a very full article and is not confined to the bacteriological aspects. Pathology and serum therapy are also dealt with fairly fully. The various serum tests are fully described. The article is very comprehensive and well written, as one would expect from a man who must be regarded as a leading authority on the subject. Our only criticism is that a good many of the details which are common in all ordinary textbooks might have been omitted with advantage to the readers, but the inclusion does not in any way minimise the value of the contribution as a whole.

The chapters on rat-bite fever, leptospiroses and yaws do not call for any special comment. They give all the important information on these diseases and give it in a very satisfactory way.

Chap xi, on the normal bacterial flora of man, is admittedly a difficult one to write, as there must be a considerable variation in different individuals not dependent on any single factor. Climate, food, etc. must all play their part. To get any standard of real value would mean a very extensive and prolonged investigation. The writers of this chapter have given us a great deal of information, and have given it well, but we cannot say that much which is either new or of real value has been added to our already rather confused store. It is perhaps well that this chapter is included to make the "System" more complete, but we cannot be enthusiastic over what is, and possibly must be, a mere compilation of observations by many authors. The authors have attempted to bring some order into the confusion which exists, and with a certain amount of success. We still are, however, very uncertain as to what are really 'normal' and 'abnormal' bacteria in the various situations in an apparently healthy man and which are to be regarded as pathogenic. The portion of the chapter on the aciduric group of intestinal organisms with which the chapter closes, is, in our view, the best part of the article, and we feel that if more had been done along these lines a more valuable contribution would have been made.

Chap xii, by J. T. Edwards, is on swine erysipelas, and gives a fairly full account of the disease and the organism concerned. J. M. BEATTIE

### Mineral Treasures in South Africa.

*Mineralische Bodenschätze im südlichen Afrika*. Von Prof. Dr. Hans Schneiderhohn. Mit Beiträgen über die Diamantlagerstätten Südafrikas von Prof. Dr. Erich Kaiser und die Kohlenvorkommen Südafrikas von Prof. Dr. Paul Kukuk. Pp. viii + 111. (Berlin • N. E. M. Verlag G. m. b. H., 1931.) 18 gold marks.

PROF. SCHNEIDERHOHN was one of those who had the good fortune to attend the fifteenth meeting of the International Geological Congress held in South Africa in 1929, the conferences and excursions in connexion with which ranged over an area extending from Cape Colony to Northern Rhodesia and from South-West Africa to Natal. Because of his special knowledge of the geology and ores of South-West Africa he acted as a director of one of the excursions to that region, conducting a large party over the mining field of Otavi, of which he had made a study in previous years. He also took part in several excursions conducted by others. During his travels he kept records of the areas visited, and on returning to Europe wrote these up into a series of articles, which were published by *Metallwirtschaft* between December 1929 and June 1930.

At the suggestion of the editor of that journal, Dr. Schneiderhohn has now elaborated these articles and assembled them in a single volume, entitled "*Mineralische Bodenschätze im südlichen Afrika*." The volume, making no claim to be encyclopædic, confines itself to fields visited by the author or by some of his German colleagues. It is divided into six sections, dealing severally with the Congress programme, excursions in South-West Africa, in the Union of South Africa, in Southern Rhodesia, Northern Rhodesia, and the Belgian Congo.

The section on South-West Africa includes a general account of the geology, and special descriptions of the mineral-bearing pegmatites of Namib, the copper-lead-zinc deposits of Otavi, the associated vanadium ores, etc. That on the Union comprises accounts of the Witwatersrand gold-field, and of the diamond, coal, and iron deposits of South Africa as a whole, the diamond occurrences being described in collaboration with Prof. E. Kaiser of Munich, and the coal by Prof. P. Kukuk of Borchum. There is also a good description of the Bushveld igneous complex and of the chromium, nickel, platinum, and tin mineralisations genetically connected with it.

Under Southern Rhodesia the general geology

is summarised, and special reference made to the asbestos and chromite mines, and to the Great Dyke and its associated ore-deposits. The section relating to Northern Rhodesia is particularly interesting. It epitomises the geology so far as is at present known, and gives good accounts of the lead-zinc-vanadium ores of Broken Hill, and of the deposits of the great copper mines—Bwana M'Kubwa, Mufulira, Roan Antelope, N'Kana, N'Changa, etc.—now in course of development. It is shown how the Rhodesian geology carries on into the Belgian Congo, and interesting accounts are given of the copper-field of the Katanga and of the remarkable uranium and radium deposits of Chinkolobwe.

The book runs to about 110 pages, and is interestingly written. It is profusely illustrated with photographs, maps, and sections, some of the maps being particularly valuable, because they represent the latest results of geological surveys now actively in progress. Although necessarily based in large measure upon the work of others, it contains much that is original either in substance or interpretation. It is a compilation which many who are interested in the geology and mineral resources of South Africa will greatly appreciate, and of which its author may be justly proud. C G C

### Short Reviews

*The Study of Rocks* By Prof S J Shand Pp xi + 224 (London Thomas Murby and Co., New York D Van Nostrand Co., 1931) 6s net

PROF SHAND has written a clear and well-proportioned account of modern petrography, which instructs the beginner along sound lines and is well worth reading by mature students. Nearly two-thirds of the book is devoted to igneous rocks, and both in this section and in those dealing with the sedimentary and metamorphic rocks, the treatment of rock-forming minerals, and classification, reveals the author's remarkable capability for adequate summarisation.

Chap. IV, on the classification of eruptive rocks, is a masterly outline of the chief systems that have been proposed from the time of Zirkel onwards, culminating in Shand's own scheme as recently developed in his larger book on "Eruptive Rocks." The difficulty of dealing with rocks that carry both quartz and olivine is met by suggesting that if there is enough quartz to convert all the olivine into pyroxene "the rock should then be considered a saturated one." A welcome feature is the recognition that there are peridotites which are definitely intrusive on their own account and seem to owe nothing to accumulation of early formed crystals from basaltic magma.

Sedimentary rocks are divided into (a) organic residues, (b) solution residues, (c) crystalline

rock-residues and (d) crypto-crystalline and colloidal rock-residues. The main classes of metamorphic rocks recognised are mylonites, hornstones, and crystalline schists, granulites and injection-gneisses are referred to under the third of these categories.

Each chapter is followed by suggestions for reading which provide a useful guide to petrological literature. The book is a model of competent compression, and should prove to be a stimulating introduction to this vast and ever-growing subject.

*The Primitive Mind and Modern Civilization* By C R Aldrich (International Library of Psychology, Philosophy and Scientific Method) Pp xvii + 249 (London Kegan Paul and Co. Ltd., New York Harcourt, Brace and Co., 1931) 12s 6d net

EARLY excursions of the psycho-analysts into the realms of anthropology did not produce any results which inspired confidence. Prof Malinowski had no difficulty in showing in his well-known examination of the hypothesis of the father-son antagonism, in the light of the customs of a matrilineal society such as the Trobrianders, that they had failed to take actual conditions into account. Mr Aldrich, a follower of the Zurich school, however, maintaining that anthropology is unable to handle its data unaided, now examines the beliefs and rituals of primitive and savage society in the light of the two principles of the 'racial unconscious' and the gregarious instinct. He attacks the school of Lévy-Bruhl and shows that, so far from the savage standing at a prelogical stage, between which and the thought processes of the civilised mind a gulf is fixed, there is in fact a regular progression from the unconscious, as manifested in an instinct for co-operation, through the conventional morality of the savage and civilised, to the consciously directed social co-operation which is now making itself manifest in certain individual members of society as the place of conventional morality is taken by what he calls 'bio-morality.'

Anthropologists will welcome Mr Aldrich's critical examination of their data, even if they do not agree with his stimulating conclusions. His 'racial unconscious' is at present no more than hypothetical. Its existence still has to be proved. At present his interpretation of social phenomena, such as reasons for purification of warriors on their return from a successful raid, is metaphysical rather than psychological, but it cannot be ignored and will stimulate further research.

*The Life of the Ant* By Maurice Maeterlinck Translated by Bernard Miall Pp 192 (London, New York, Toronto and Melbourne Cassell and Co., Ltd., 1930) 6s net

THIS book completes the author's trilogy—"Lives" of the bee and the white ant being already well-known works from his pen. Much personal observation has been drawn on for the compilation of this volume, and scarcely a page passes without reference to a prominent myrmecologist, whose views are freely discussed. We read of the habits of ants, their social sense, their community

foundation, their adaptability, and their warfare. But so complicated and so biologically big is this communal life that the author appears really to be "writing not the history of a community but the chronicles of a hundred nations."

Ants probably began as insect hunters, and from this predatory life they evolved through the pastoral to the agricultural method of life, thus affording a parallel to the three stages of human history—conquest, defence, industry. What is the secret of this wonderful evolution? We are told that it is rooted in the capacity to live in social communities, and with this capacity has developed a 'mob intelligence' far surpassing that of the individual. Social organisms are endowed with a social organ. For man it is the brain, while for the ant it is a stomach sac used for food storage, and from which regurgitation takes place in response to a caress—that touch of Nature which makes the whole world kin. Their powers of communication—the author suggests the power of speech—and of orientation have been the subjects of research for many naturalists. These powers are seated in the antennae, organs largely concerned with olfaction, but also, we are told, they are endowed with electric, magnetic, etheric, and psychic perceptive ability. The general point of view is distinctly anthropomorphic. The book is delightfully written and beautifully translated.

*The Electrical Equipment of Automobiles a Book on Principles for Motor Mechanics and Motorists* By Prof S P Smith. Second edition, revised and enlarged. Pp xii+198 (London Chapman and Hall, Ltd, 1931) 5s net.

THIS excellent little book, the outcome of lectures given by Prof Smith at the Royal Technical College, Glasgow, contains just what is required by the motorist who has an elementary knowledge of electricity and wishes to understand the electrical equipment of his car. Its seven chapters deal with the storage battery, the action of electrical machines, the starting motor and the dynamotor, the charging generator and the automatic cut-out, miscellaneous electric equipment, wiring systems and location of faults, and the ignition system.

Explanations in simple language are given of the principles and construction of the various equipments, their action is explained, hints as to their proper use are given, and the likely faults are tabulated, together with the appropriate methods of detecting and remedying them. A study of the book will go far towards heightening the interest of the motorist in the many ingenious pieces of apparatus which discovery and invention have placed at his service.

*Introduction à la géométrie projective différentielle des surfaces* Par Prof Guido Fubini et Prof Eduard Čech. Pp vi+291 (Paris Gauthier-Villars et Cie, 1931) 60 francs.

ALTHOUGH the metrical part of differential geometry has been studied for two hundred years, the projective aspect received little attention until much later. Perhaps the earliest work on the subject was that of G H Halphen in 1875, but the

systematic investigation of the projective differential geometry of surfaces was commenced by Wilczynski about 1906. Since then a great deal has been done, especially in Italy and the United States.

A good account of the history and present state of knowledge is given in the book under review, the authors of which have themselves published many researches in the subject. After an introductory chapter there follow two chapters on curves in the plane and in space. The remaining eleven chapters deal chiefly with surfaces, including an account of Cartan's methods. In addition to historical and bibliographical notes at the end of nearly every chapter, there is an extensive list of research papers, occupying thirty-four pages. It is regrettable to find that among all these papers there is only one by an English author. Possibly this book and the larger Italian treatise in two volumes by the same authors will stimulate the study of projective differential geometry in Great Britain.

H T H P

*Problems in Practical Physical Chemistry* By F A Philbrick (Dent's Modern Science Series) Pp xiii+146 (London and Toronto J M Dent and Sons, Ltd, 1931) 3s 6d.

MR PHILBRICK'S book is a joint product of the Oxford school of physical chemistry and of teaching experience at Clifton. In the narrow compass of 146 pages, and at a very modest price, it includes instructions for 33 problems, on reactions, ionic equilibrium, the phase rule, distribution, reaction velocity, electrical conductivity, and indicators. One obvious merit of the book is that a number of exercises in volumetric analysis are set in the form of a physico-chemical problem instead of a mere exercise in analysis, since the student is required to find out the nature of the interaction in question. This procedure not only provides useful experience of chemical methods, but is also a very welcome relief from the too highly standardised exercises which have done duty for a generation in practical courses of physical chemistry.

*Villages et Kasbas berbères tableaux de la vie sociale des Berbères sédentaires dans le sud du Maroc.* Par R. Montagne. Pp ix+22+iv+73 planches (Paris Félix Alcan, 1930) 50 francs.

IN this volume, Dr Robert Montagne has given his readers, literally, a panorama of social development in Morocco according to his interpretation of certain aspects of material culture. The text is reduced to a minimum, the information is conveyed by a series of excellent photographs. In these are shown the different types of villages, fortified and unfortified dwellings, granaries, hill-forts, and structures of a like character, each of which is regarded as appropriate to some phase of the history of the country, ranging from the small independent agricultural community to centralised government through the agency of local governors or tributary chief. The photographs are arranged in groups accordingly, each group being preceded by a brief general account of the social phase it illustrates.

## Electron Optics.\*

By Prof G P THOMSON, F R S

ALMOST all progress in physics has come from comparing the unfamiliar with the familiar. One could scarcely have a better example than the story of Newton's apple—for this comparison assimilated the motion of the moon to the motion of a falling body. The great essential is to use an idea with which one is already familiar. It is less important that the idea should be really understood—if, indeed, anything in the physical world ever can be understood in any absolute sense. The falling of the apple was not understood then (one may perhaps doubt if we understand it much better now, when we say that it is a consequence of the curvature of space), but it was at least familiar, and the mind needs familiar images with which to work.

Now, in the study of the very small there are two pictures which have proved their use. One is as old as the Greeks—the idea of a particle, hard, small, smooth, an idealised grain of sand. Generally it is pictured as moving, and the universe as an endless game of snooker with every ball played at once. The other view is only seven years old, but it is a promising youngster and in the last few years has come to take an equal place with its elder brother, so producing a curious duality in our views of matter. I refer to the idea of matter as waves, which was invented by Louis de Broglie. Now, light has long been regarded as waves, and to many physicists, at least, waves of light are more familiar in their properties than the more tangible waves of water or of sound. This analogy between matter and light is a good one, but, like all analogies, there are points at which it fails.

According to de Broglie, any piece of matter should have wave properties, but in most cases the wave-length would be too small to detect, even with the most refined experiments. The heavier the piece of matter and the faster it is moving, the shorter is the wave-length, and although recently the wave properties of atoms as a whole have been detected, most of the experimental work has been done with the lightest known pieces of matter, namely, electrons. Even with these, the wave-length is usually much less than that of light. Thus for the electrons which form part of a beam of cathode rays from a discharge in rarefied air, the wave-length is usually about one fortieth of the size of an average atom, and only about one hundred-thousandth of the wave-length of red light. Actually, if the voltage is 30,000 volts, the wave-length is about  $7 \times 10^{-10}$  cm.

The characteristic feature of those waves which one can actually see and feel is the periodic motion of the water or other medium, but when one comes to waves in which one can no longer actually see the medium bobbing up and down, the most characteristic wave property is that called 'interference'. This is the property by which, for example, two beams of light can produce darkness, and is explained at once as due to the superposition of two

trains of waves in such a way that the crest of one wave neutralises the trough of another.

In the case of light, this leads to a pattern of light and dark bands, the sharpness of which may be much increased by using not two waves only but a large number of wavelets produced by the scattering of a single wave from a number of obstacles arranged in a regular order. To get a satisfactory pattern, the distance apart of the scattering objects must not be too great compared with the wave-length of the light. This led Laue to use the atoms of a crystal as scattering centres to measure the very short wave-length of X-rays. The use of a crystal, however, introduces a complication, for we are not only concerned with the wavelets from one plane of atoms but also with those from successive planes. The result is that only if the crystal is correctly adjusted to the incident beam will there be a strong beam selected by interference. If the crystal is powdered and the pieces are arranged at random in the path of the rays, there will always be some pieces correctly adjusted, and the beams from them will lie on cones and their intersection with a screen will show as rings. The absolute sizes of the rings are proportional to the wave-length and inversely as the spacing of the atoms, while the relative sizes of the different rings in any one experiment depend on the arrangement of the atoms in the crystal.

Now, electrons are certainly scattered by atoms. If they are like waves, they should give interference and the scattered waves should be concentrated in certain directions, presumably the electrons will show themselves most where the waves are concentrated. In my early experiments, this was done by passing a narrow beam of cathode rays through a thin foil and receiving the scattered rays on a photographic plate. When developed, these plates showed ring patterns which were in agreement with those calculated from de Broglie's theory and the known crystal structure of the metal films used. To get good results the films had to be of the order of  $10^{-6}$  cm, and this limits the substances with which one can work. I have found, however, that equally good results can be got by reflecting the rays from a block of material, the face of which has been suitably prepared. It is probable that the rays pass through minute projections on the surface, so that the reflection is only apparent. In this way ring patterns have been obtained with a variety of substances, such, for example, as spluttered metals and metals which have undergone surface oxidation or other chemical change. The method enables one to examine a very thin layer of the substance, for the effective depth of penetration is of the order  $10^{-6}$  cm. It appears that almost any surface will give some kind of a pattern, providing that it is reasonably flat.

The concentration due to interference is, as we have seen, much more marked if there are many scattering centres arranged in order. This is so in

\* Friday evening discourse delivered at the Royal Institution on Dec 4

the case of the above experiments, for though the crystals are small enough to be very numerous, even in a small piece of material, they each contain a very large number of atoms. Recently, Wierl has made experiments of the same character with gases. Here the scattering particles are the atoms, of which there are only a few in each molecule, so though rings are formed, they are not very sharp. Nevertheless, the theory holds, and Wierl has calculated the distance apart of the atoms in various molecules from the sizes of the rings. He has been able to draw a number of interesting conclusions about the relative positions of the atoms in the molecules. For example, he finds that the carbon atoms in the benzene rings lie in a plane. Mr French has recently found similar diffuse rings from the polished surfaces of metals. These rings appear to be due to the noncrystalline Beilby layer.

The apparatus I have described will also serve for single crystals. Here, however, we should expect nothing unless the crystal were suitably adjusted, and then only a small number of spots. With a cleaved surface of rock salt these expectations are approximately fulfilled, though there is enough latitude from various causes for some sort of a spot to appear for almost any setting of the crystal. In addition, there appear a number of black and white lines, which have been ably explained by the discoverer, Kikuchi, as due to double scattering.

Some experiments with single crystals of metals have led to rather surprising results. When cut so that the face is crystallographically a simple one, these crystals give an extended pattern of spots of a very regular character. The pattern is just what we expect from a single layer of atoms arranged in the crystal form and set normal to the rays. The agreement is exact and extends to small details. The pattern is the polar reciprocal of the atomic arrangement known to exist in the crystal, each spot of the pattern corresponds to a line of atoms in the crystal, and the whole plane of atoms behaves like two crossed optical gratings. Clearly, however, a single plane of atoms sticking out at right angles to the main surface is a mechanical impossibility. The surface was actually prepared by etching and was probably covered with pits and pyramids, through which the electrons pass. The reason for the extended pattern is that the thickness in the path of the rays is so small that the successive layers of atoms are not badly out of step over a considerable range of angle. This approximate agreement is helped by the small angle through which the rays are turned out.

Some recent work in conjunction with Mr Stuart on spluttered platinum films has shown that while the usual structure is that of normal platinum, abnormal types sometimes occur. One of these gives a pattern of straight lines, which is unstable and disappears under the action of the rays. It appears to be due to the presence on the surface of small pieces of some crystalline structure in which the atoms are arranged accurately in layers parallel to the surface but each separate layer is largely chaotic. We have not been able to determine whether the atoms are those of platinum or of a

gas. Another abnormal structure shows the presence of extra rings, which may be associated with catalytic activity of the platinum.

While these experiments show the close resemblance between the behaviour of the electrons and that of light in those experiments which were the original proof of its wave character, yet, all the same, one must not entirely abandon the particle idea. When the electron reaches the photographic plate, it seems to forget that it is a wave and becomes a particle. If the plate were examined under a high magnification, the pattern would show up as a number of black specks, each corresponding to one

FIG. 1.—Diffraction pattern formed by electrons reflected from a cube face of a silver crystal. The interrupted line was added afterwards.

grain of silver bromide made developable. Each electron affects one grain only. Yet the waves which interfere must have been scattered from atoms over a wide front, and the sharpness of the ring and spots shows that there has been a long train of waves acting, just as a sharp line in an optical spectrum implies a long train of coherent waves. On the wave side of its nature the electron is a widely extended entity which in a sense occupies the whole region in which it might be found. An electron is like an able guerilla leader who occupies a wide area with rumours of his presence, but when he strikes, he strikes with his whole force. No analogy is perfect, and though the analogy between light and electrons even extends to this curious duality of wave and particle, it breaks down in the end.

Electrons are essentially different from light. They are acted on by electric and magnetic forces, and react on the bodies which cause these forces. Light does not—it only affects matter when it actually hits it, there is no action at a distance. Further, the electronic waves are a trifle less real than those of light. No one, it is true, has ever actually observed the frequency of visible light, but that of very long wireless waves can be directly followed, and the difference must be only one of degree. Now, so far as we know at present, the frequency of electron waves is quite unobservable. It is always the wave-length which we find. Possibly we could observe differences of frequency under

very special conditions, but the absolute values seem to have no significance except as mathematical symbols. Different values can be assigned to this frequency, and the calculated results still agree with experiment.

Again, the fluctuating quantities or 'displacements' in the light wave have a definite physical meaning, namely, electric and magnetic intensities. No one has observed the corresponding quantity in the electronic wave. Indeed, in the most suc-

cessful forms of the theory it is not even a real number. Only the intensity of the wave has a physical meaning, namely, the chance that an electron will appear at the place in question. The two views of electrons, as particle and as wave, are parables, each enshrining a part of the truth. Whether between them they include all that we need to know, as some physicists believe, or whether there are not other aspects, still undreamed of, is for the future to decide.

### Dental Caries and Diet.

THE researches of Mrs Mellanby on the part played by diet in the development of the teeth and jaws in animals have already been referred to in these columns<sup>1</sup>. A report on the relationship between diet and the structure of human teeth is in course of preparation. Mrs Mellanby's work has also led to the conclusion that it is possible to influence the structure, and thereby the resistance to disease, of teeth after eruption. It was obviously desirable that this conclusion should be confirmed by a large-scale clinical trial. A preliminary report of such a trial has now been issued by the Committee upon Dental Disease<sup>2</sup>.

The investigation was carried out at three residential institutions for children near Birmingham, under the control of the poor law and later the local education authority. The teeth of the children were examined every six months by Mr A Deverall; the diets were controlled by Miss E Brinton and Miss M Reynolds. The number of children included in the investigation was 332, aged from 5 years to 14 years; the duration of the test was two years. The children were divided into four groups, all of which were on a similar and generous basal diet. At the first institution 1-1 5 oz treacle daily was added to the diet, at the second 1-1 5 tablespoonfuls (14-21 c c) daily of olive oil to that of one group and a similar amount of olive oil containing radiostol (irradiated ergosterol) to that of the remaining children, at the third institution the addition to the diet was 14-21 c c cod-liver oil daily.

The dental examination made at each inspection included the number and structure of the fully erupted teeth, the condition as regards caries, of which three degrees were arbitrarily recognised, and the condition of the gums. By using a numerical notation for the degree of caries, it was possible to obtain the total caries figure for any group of children, and also the average caries figure by dividing the total by the number of teeth in the group. All teeth lost subsequent to the first inspection continued to be counted in later inspections, since otherwise the extraction of a carious tooth would appear to lead to a sudden improvement in the condition as regards caries. The incidence of caries in a group was shown by the number of carious teeth; the extent of caries by the average caries figure. The latter could only show a decrease when the number of teeth in the group increased by the eruption of fresh teeth, which were not attacked,

or only slightly, by caries, since the total caries figure could not decrease with the passage of time.

The investigation reported was actually carried out in two parts: in the first the effects of adding treacle, olive oil, or cod-liver oil to the diet were compared, in the second the effects of olive oil and radiostol. The olive oil group was to a large extent the same in each investigation. Each group consisted of 65-85 children. The results obtained were briefly as follows: the increase in the percentage of carious teeth in the group given treacle was 10, in those given olive oil 8, and cod-liver oil 3, in the first experiment, in the second the olive oil group showed a percentage increase of 7 and the radiostol group one of 2. The percentage increases of the average caries figures for the five groups were respectively 42, 46, 10, 31, and 10. Statistically, all the differences are significant except that between the average caries figures in the second experiment. Further analysis of the figures indicated that similar differences were observed when the deciduous teeth, the permanent teeth or the first and second premolars (upper and lower), or first permanent molars (upper and lower), were considered separately. In the first investigation the actual number of carious teeth approximately doubled at the institutions in which treacle and olive oil were the dietary supplements, but only increased 50 per cent when cod-liver oil was given. In the second investigation the number of carious teeth per child rose from 4.5 to 6.2 in the radiostol group and from 3.8 to 6.4 in the control group, for the permanent teeth the figures were 1.8-3.1 and 1.6-3.7 respectively. Very similar figures were obtained in the first experiment.

Considering the two investigations together, it was found that the increase of the average caries figure of the permanent teeth in the two vitamin groups was about two-fifths of that in the control groups. In general, the results agreed closely with those previously obtained at Sheffield with a smaller number of younger children suffering from surgical tuberculosis and showing a higher initial incidence of caries.

It appears, therefore, that the addition of vitamin D to a standard dietary will reduce the increase in the incidence and extent of caries, which occurs with the passage of time, by about two-thirds.

## Obituary.

MAJOR-GENERAL SIR DAVID BRUCE,  
K C B, F R S

SIR DAVID BRUCE was one of the greatest of the great physicians who deal less in healing of the sick than in the conquest and abolition of disease, he died of a dread disease on Nov 27, in the seventy-seventh year of his age. His one fear had lately been lest his wife, the comrade of fifty arduous years, should be left helpless, but her release from suffering came four days before his own.

Born in Melbourne (on May 29, 1855) but brought home to Scotland at five years old, Bruce went to Stirling High School, and was sent out into the world, by way of a Manchester warehouse, at the age of fourteen. There he worked for about three years, during which time his wish was to become a professional boxer or footballer, an ambition which those can understand who remember his great figure and his prodigious strength when he was young. About the year 1876-77 he came to the University of Edinburgh and began to study medicine, soon afterwards he was foremost in a little band of friends, of whom Diarmid Noel Paton the physiologist was one, and another helps to-day to write these words. We worked together, fifty-three years ago, at the same table in Turner's old dissecting-room, the ways and appurtenances of which had scarcely changed in two hundred years, and then stepped across the street to see Lister turn up the cuffs of his black frock-coat, and operate under the spray.

Immediately after graduating, Bruce joined the Army Medical Service in 1883, and in the same year he married Mary Elizabeth Steele, a doctor's daughter, of Reigate. The marriage was singularly fortunate. Mary Bruce was a rare helpmeet, tireless and fearless, ready at any moment to follow her husband across the world, growing more and more skilled in all the delicate manipulations of bacteriology, and possessed of no little scientific insight and acumen of her own. Bruce was never tired of praising her, of acknowledging her help, of testifying to her knowledge and ability. Almost his last words were to remind a friend that the story of his own life was never to be told without full credit being paid to Mary for her part therein.

Bruce was a fervid admirer of Pasteur, all his life long. It was Pasteur's example which he followed steadily, to make of medicine "an experimental biological science", and to arrive at "the intelligent, purposive prevention of disease". Pasteur's epoch-making work was already something of an old story when Bruce was a student, but another great epoch was just beginning, with Laveran's discovery of the malaria parasite in the blood corpuscles, and with Koch's discovery of the tubercle bacillus.

In Bruce's presidential address to the British Association at Toronto—an address which seemed to relate every salient fact of modern medicine within the brief compass of an hour—he tells how one day in 1882, in Edinburgh, he heard of Koch's

great discovery from a fellow-student just home from Germany. So revolutionary an idea was hard to believe at first, but Bruce sketches the interest and excitement it aroused, in which he shared to the full. The excitement continued for within two years more the bacilli of glanders, diphtheria, typhoid, and cholera had all been discovered in Koch's laboratory. By this time, in 1884, Bruce—an Army surgeon and a married man—was at work in Malta, and so well did he follow Koch's and Pasteur's example that by 1886 he had discovered *Micrococcus* (now *Brucella*) *melitensis*, and proved it to be the actual cause of Malta (or Mediterranean) fever. This was a cardinal discovery. The bacteriologist of to-day, with his well-stocked laboratory and the experience of fifty years behind him, may well pay tribute to Bruce's splendid insight, which let him see how, by cultivation of a micro-organism from a patient's blood, evidence could be got of the direct relation between the organism and the disease. Bruce went straight to the root of the matter, and his method of blood-culture, a commonplace of to-day, was a pioneer procedure then. The work was done against almost insuperable technical difficulties, the observations were repeated again and yet again. At last, after many disappointments and set-backs, Bruce succeeded in reproducing the disease among his experimental animals.

The discovery of the causal agent of a communicable disease often helps but little towards the finding of means for its prevention, but in this case Bruce's indomitable energy had its ultimate reward. For seventeen years after the discovery of *M. melitensis*, Malta fever continued to prevail. "Almost every sailor who came into hospital even for the most trivial complaint took Malta fever, and after a long illness had to be invalided home." At last the Admiralty and the War Office took alarm, and Bruce was sent out again by the Royal Society, in 1904, at the head of a Commission. After months of hard and disappointing work, Dr Zammit, a Maltese colleague, happened to examine the blood of a goat—an animal which had been already and repeatedly found immune to the disease, but now it turned out that the goat's blood 'agglutinated' or 'clumped' the micrococcus—a fact which Bruce took to mean that the organism must have been living and multiplying within the apparently healthy goat before this peculiar property of its blood could be brought about. Work went on with new hope and energy, fifty per cent of the island goats were found to carry the micrococcus, and a fifth part of these were actually passing it into their milk. Maltese milk was at once struck out of the dietary, and "from that day to this", said Bruce, "there has scarcely been a case of Malta fever in the garrison. The disease had been blotted out at a single blow." This conquest of Malta fever is one of the greatest, most unequivocal successes of preventive medicine.

In 1894, Bruce began his long study of the

trypanosomes, and the story of his investigation of these, and of the diseases of man and beast which are associated with them, is the chief story of his life. In 1895, a severe epidemic of nagana among the native cattle of northern Zululand was reported to the Natal government. Bruce happened to be stationed in Natal, and Sir W. Hely-Hutchinson, the governor, a wise and friendly man, put the task of investigation into his hands. So Bruce and Mary started off on their long trek by ox-wagon to the scene of the outbreak, and the first thing they did was to discover trypanosomes in the blood of the infected animals. Bruce was a first-class naturalist, he had learned the art of outdoor observation on the Ochils as a schoolboy, and on the Grampians in his college years, and his next step, after discovering trypanosomes in the infected blood, was the work of the naturalist rather than of the physician. There happened to be a 'fly-belt' hard by Bruce's camp, between the high ground and the sea, and Bruce, knowing (as every Scotch boy did) all that David Livingstone had to tell about the tsetse fly, took it into his head to see what actually happened when a beast was bitten by the fly. Natives were told to drive their cattle into the fly-belt, and when they came home it was with no little surprise that Bruce found the blood of the fly-struck animals to contain the nagana parasite. But the natural history of the case was not yet all told. The next thing was to seek and to find the same trypanosome living, but living harmlessly, in the wild game of the country—in antelope and buffaloes, which had become, like the Maltese goats, immune to the disease. Bruce had to do all this work with the most primitive appliances, but he surmounted every difficulty. At last, not only was the specific trypanosome (*T. brucei*) of nagana discovered and its relation to the disease established, but the precise way in which *Glossina morsitans* propagated the disease was made clear. This was the first demonstration of the transmission by an insect of any protozoal disease. It won for Bruce his fellowship of the Royal Society in 1899.

It had needed keen insight and a wide outlook to discern how the wild game of the region might act as a reservoir of infection, and it took a deal of hard work to prove that it did so. Later on, when Bruce came to study sleeping sickness in mankind, the lesson so learned of the possibility, or probability, of the malady lurking continually among the huge herds of wild animals must have seemed to him, lover of animals as he was, an appalling problem.

In 1903, not long after the Boer War was over, Bruce, together with his wife and Dr. David Nabarro, went out to Uganda (again at the instance of the Royal Society) to continue and extend Castellani's work on sleeping sickness, done in the year before. The needful clues were now all in Bruce's hand. He knew that trypanosomes had been found in the cerebro-spinal fluid of sufferers from the disease, and his experience told him that the infection was most likely due to a blood-sucking fly, probably to one of the *Glossina* species. How he showed that the area occupied by *Gl. palpalis* and

that infested by sleeping sickness were one and the same, is a romance of science.

Bruce was walking through the forest paths one day with the king of the country, telling him about the fly and its effects, and explaining how useful it would be to know just where the fly lived and how far its range extended. The king listened with great attention, then whispered to his viziers, who in turn slipped one by one from the pathway into the bush. Here on either side, silent and unseen, were the king's attendant messengers, and before Bruce had come to an end of his story these men had set off to all parts of the country, with the king's command that the tsetse flies should be sought for, and brought in from wheresoever they should be found. It was a triumph of organisation, and the dusky king shares the credit with the investigator, it was also a complete scientific success. The remarkable fact had already been discovered that the disease kept to the islands and to a narrow belt of country by the shore of the lake, in no part of Uganda were cases found more than a few miles from the lake shore. It was now shown that the distribution of the disease was identical with that of the tsetse fly, where there was no fly, there was no sleeping sickness.

Bruce came home in the autumn of the same year, 1903, but went out to Uganda again five years later, in order to work at the life of the parasite within its insect-host. He found out, among other things—and it must have been a sad disappointment to him—that many animals can harbour *Trypanosoma gambiense* over long periods, a fact which could only mean that the prevention of sleeping sickness was a well-nigh insoluble problem. He found also that *Gl. palpalis* was the insect-host, or 'vector', not only of *Tr. gambiense*, but also of sundry other trypanosomes besides, and his careful descriptions of these species, and their varying behaviour within the insect-host, were very helpful to the next workers in the field. His last work on this subject was done in Nyasaland, between 1911 and 1914, as head of a commission on trypanosome infections of man and animals in that territory. He came to the conclusion that the human trypanosome of Nyasaland was not identical with *T. brucei* though its vector was *Gl. morsitans*. It is perhaps still an open question whether this trypanosome (commonly called *Tr. rhodesiense*) and *T. gambiense* may not both of them be mere varieties of Bruce's own nagana trypanosome, *T. brucei*. Bruce showed often in his later talk how glad he would have been to go out once more, to solve this final problem.

There is far more to tell of Bruce's great and crowded life than can be told here. Happening to be in Ladysmith during the siege, he turned his hand to surgery, with conspicuous success, and with such love and devotion did he sometimes speak of this part of his life that one felt that a great surgeon had perhaps been lost to make a still greater scientist. His wife became a nurse at the same time, and stood beside her husband in his tireless labours, she earned the Royal Red Cross thereby.

Soon after the beginning of the War in 1914, tetanus made its appearance among the wounded, in so alarming a way that no time had to be lost in grappling with the danger, among many thousand wounded (however slight their injuries might be) some 9 or 10 per cent were attacked by tetanus, and no less than 85 per cent of all those affected died. A committee was appointed in haste, with Bruce at its head, and this committee made the crucial discovery that if the appropriate serum (Kitasato's famous *antitoxin*) be administered *at once*, the wound will lead to no lockjaw symptoms. As Bruce put it, there were 2500 cases of lockjaw in the British Army during the War, and 550 deaths, there would have been 25 000 cases and 20,000 deaths, had matters been allowed to go on as they were during the first months of the War, without the prophylactic serum injections.

During the War, Bruce was Commandant of the Royal Medical College, where his knowledge and immense experience were put to good use in controlling the many varied and even divergent activities of that place. He became chairman of a War Office Committee on Trench Fever, as he had been before of that on tetanus, and once more his driving power and his own industry helped and hastened the investigation. Doubtless a large part of the work was done in this case by others, but the success was just as complete as in the other cases where Bruce worked alone. It was amply proved that the louse, and the louse alone, was to blame for spreading the disease, and (as Bruce said in his Toronto address) this meant that very soon trench fever would have been abolished on the western front. In 1917 it had been the cause of some 20,000 out of a total of 100,000 admissions to hospital in the British Second Army alone.

Besides his scientific work, Bruce played many lesser but important parts. He was president of the Physiological Section of the British Association at the South African meeting in 1905, and president of the Association at Toronto in 1924. He was president of the Royal Society of Tropical Medicine from 1917 to 1919, editor of the *Journal of the R A M C* from 1904 to 1908, Croonian lecturer at the College of Physicians in 1915, and chairman of the governing body of the Lister Institute from 1916 until his death. Honours came to him in their course, and he wore them proudly, as a soldier should, but at heart he was always the humble student, and the untiring friend and helper of younger men.

Bruce's scientific imagination and intuition were as fine as the simplicity of his heart. He had had little of what we understand by laboratory teaching, little or no apprenticeship to research, in Edinburgh fifty years ago, but he had Lister's great example constantly before him, and Pasteur's to think of, and Koch's to learn of later on. He needed no more than these, and his own brains, to enable him to attack the problems which presently faced him, with all the skilled assurance of a master-hand. He had the gift which belongs to the greatest of scientific men, the true Faraday gift, of putting plain questions to

Nature never two at one time, and always such as she can answer in simple words. His imagination kept him always one step ahead of his observations, his judgment told him where that step should be, energy spurred him on, and the shrewdest common-sense held him back from unsafe conclusions. He took no regard of riches, he was contented to be poor, but his face was set like flint towards his one ambition, the victory over disease.

Those who knew Bruce best found him stern but most lovable, *sans peur et sans reproche*. His heart went out to all those in sorrow, need, or sickness. He closed his Toronto address with solemn words: "We are all children of one Father. The advance of our knowledge of disease is not for the benefit of one country but for all—for the lonely African native, deserted by his tribe, dying of sleeping sickness in the jungle, or the Indian or Chinese coolie dying miserably of beri-beri, just as much as for the citizens of our own towns."

"It is the duty of science", he said (it was his own rule of life), "to go steadily forward, illuminating the dark places in hope of happier times." He never turned aside or knew discouragement. "On, on, and no regrets", was a phrase he often used, it had been his own watchword, and he passed it on, to be a warning and an encouragement to men who had their lives to live.

Bruce died poor and sorely stricken, he had had his troubles and perplexities withal. But he had also (like Greatheart in the story) had the golden hours when great things happen, and they had brought him the supreme reward of triumphant and beneficent discovery.

D W T  
W J T

THOUGH David Bruce, whose recent death removes from the field of tropical medical research one of its most brilliant investigators, made discoveries of the utmost importance in connexion with Malta fever, for which he was elected a fellow of the Royal Society in 1899, his name will ever be associated with Africa, that dark continent where mysterious and dread diseases of both man and animals had brought ruin to expeditions of explorers and loss of hope and too often death to those attempting its development. Malaria and black-water fever, yellow fever and sleeping sickness took their toll of human lives, while tsetse fly disease or nagana and other obscure maladies wrought havoc amongst the domestic stocks, frequently wiping out in a few days the entire animal transport of some luckless adventurer. It is for his work on two of these diseases, nagana and sleeping sickness, that David Bruce attained his world-wide reputation.

Having been sent to South Africa in 1894 from the post of assistant professor of pathology at Netley, Bruce was requested by the Governor of Natal in 1895 to proceed to Zululand to investigate an outbreak of nagana amongst the cattle. Arriving at Umbobo after an arduous journey, any weaker man would have regarded the usual wattle and daub hut provided for living-room and laboratory as quite inadequate accommodation, not so David Bruce, who, with his courageous and gifted

wife, began that long series of researches the results of which have served as the foundation of all work on trypanosomiasis. His reports are models of what such reports should be, and display a logical sequence and an inductive reasoning which are remarkable. Published for the most part in the *Proceedings of the Royal Society*, they are brief and concise statements of the experiments and observations and the results obtained, the one following the other in such order and leading so inevitably towards the goal that one feels there must have been, as Col Hamerton has written, "an undefinable intuition almost mystical in its working".

Shortly after reaching Umbobo, Bruce discovered in the blood of sick animals a trypanosome similar to the one seen by Timothy Lewis in rats in India in 1878 and by Griffith Evans in 1880 in horses and camels suffering from surra in the same country. He demonstrated the pathogenicity of this organism, its transmission by tsetse flies, and its occurrence in the game, which appeared to harbour it without injury to themselves and to be mere reservoirs. In 1896 he sent to England a dog infected with the trypanosome, which was investigated by Plimmer and Bradford, and named *Trypanosoma brucei* in honour of its discoverer. This strain, handed on to other laboratories, was the starting-point of a long series of important investigations. On his work in Zululand, Bruce published a Preliminary Report in 1895, a Further Report in 1897, and an Appendix to the Further Report in 1903. His work was interrupted by the South African War, during which he distinguished himself at the siege of Ladysmith.

In 1902 the Royal Society had sent to Uganda a Commission to study sleeping sickness, and Bruce was requested to take charge at the beginning of 1903. Again accompanied by his wife, he went to Entebbe, where he was informed by Castellani, a member of the Commission who was on the point of leaving for England, of his discovery at the end of 1902 of trypanosomes in the cerebro-spinal fluid of sleeping sickness cases. Further investigation during the remaining three weeks of Castellani's stay showed that the trypanosome could be found in a large percentage of the cases, and it was quickly realised that it was the causative organism. Experiments with the tsetse fly, *Glossina palpalis*, allied to *Glossina morsitans* (or *Glossina pallidipes*), with which he had worked at Umbobo, enabled Bruce to demonstrate that it was the vector of the trypanosome, which proved to be *Trypanosoma gambiense*, described by Dutton in 1902 from the blood of an Englishman who was suffering from fever after having spent six years in the Gambia.

Bruce returned to England towards the end of 1903 and was occupied with other work until 1908, when he returned to Uganda to continue his investigation of sleeping sickness. Though, working with tsetse flies captured in the open, he had effected transmission of the trypanosomes of nagana and sleeping sickness, he adhered to the view that this was a mechanical process, the tsetse fly carrying on its proboscis infective blood for a comparatively

short time. Kleine, working with tsetse flies raised from pupæ, was able to demonstrate in 1909 that, fed on infected animals, they quickly lost their power of transmission, but that this was regained after an incubation period of about twenty days. This important discovery was soon confirmed by Bruce, who studied in detail the behaviour of the trypanosome in the tsetse fly and traced its course during the incubation period from the stomach, where it had passed with the ingested blood, back again to the proboscis and thence into the salivary glands, where the flagellate renewed its trypanosome form which it previously lost, and was then, and not until then, infective.

Bruce further studied the trypanosomes of domestic animals and their transmission, and proved that in their case also an incubation period was necessary in the fly, but that the cycle of development was not always the same. The trypanosome of nagana, *Trypanosoma brucei*, had a cycle like that of *Trypanosoma gambiense*, but *Trypanosoma congolense*, referred to by him as *Trypanosoma pecorum*, did not invade the salivary glands but remained in the proboscis after its return from the stomach, while *Trypanosoma vivax* made no return from the stomach, the only forms developing being those which lodged in the proboscis when the fly took up infective blood, the whole development occurring in the proboscis alone. These differences in behaviour in the fly enabled Bruce to classify the pathogenic trypanosomes of Africa in three groups, headed by *Trypanosoma brucei*, *Trypanosoma congolense*, and *Trypanosoma vivax* respectively. The other representative of the first group was *Trypanosoma gambiense*, and those of the other groups allied forms, several of which he had himself discovered.

David Bruce left Uganda in 1910, and in 1913 went to Nyasaland to study *Trypanosoma rhodesiense*, which had been found to produce in man a disease more quickly fatal than sleeping sickness. These studies led him to the conclusion that *Trypanosoma rhodesiense* was no other than *Trypanosoma brucei* of nagana, which was inoculated to domestic animals and occasionally to man by *Glossina morsitans*, a view which was in agreement with that expressed by Kinghorn and Yorke in 1912 from the Luangwa Valley but opposed to that of the great German investigator Kleine, who believed and still believes that *Trypanosoma rhodesiense* and *Trypanosoma brucei* are distinct.

The above account gives but a poor conception of the extent of Bruce's work on trypanosomiasis. It does not deal with the many obstacles and difficulties which his indomitable will was successful in overcoming. It states in briefest outline the main results achieved, each being the outcome of carefully planned experiment and laborious investigation—each trypanosome encountered being subjected to the same exhaustive tests and critical observations. The work of David Bruce in Africa is not only of the highest scientific value but also has a definitely practical bearing in that it has shown the way to the eradication of a group of most serious diseases.

It has already been mentioned that Lady Bruce, who died a few days before him, was his constant companion. No account of the work of David Bruce would be complete, as he himself insisted, without some reference to the important part she played. Being a skilled microscopist and artist, with a practical knowledge of the details of laboratory technique, for which she had a greater patience and aptitude than her husband, she shared the work with him, indeed, to such an extent that it is difficult not to regard David Bruce and his wife as a single unit and to conclude that neither would have achieved success without the other. They worked alone, without help, in Zululand, but on other Commissions were accompanied by various collaborators, whose part in the work was duly acknowledged in the reports and who contributed in no small measure to the success of the expeditions.

C M WENYON

WE regret to announce the sudden death, at his home in Liverpool, of Mr Andrew Scott, on Dec 27, at the age of sixty-three years. Mr Scott had been on the scientific staff of the Lancashire and Western Sea-Fisheries Committee since 1895, and, at the time of his death, was working in the University of Liverpool, mainly on the plankton collections made by the *Discovery* in the Antarctic Ocean. He had a quite remarkable knowledge of Crustacea, and, with his father, the late Dr

Thomas Scott, had described collections of Copepoda from all parts of the world. He is survived by his widow and a son and daughter.

DR JOHANN KIAER, professor of palaeontology in the University of Oslo and head of its Palaeontological Museum, died on Oct 31, at the age of sixty-two years. Dr Kiaer was distinguished for his work on the palaeozoic formations of Norway and Spitsbergen and for his descriptions of their corals, trilobites, and, especially, the Silurian and Devonian fishes. He had often visited Great Britain, where he will be deeply mourned by many friends.

WE regret to announce the following deaths.

Mr James Ford, superintendent of the Radcliffe Science Library, Oxford, on Dec 18, aged seventy-four years.

Dr Edward H Jenkins, formerly director of the Connecticut Agricultural Experiment Station, who carried out important work on the culture, curing, and fermentation of tobacco, on Nov 7, aged eighty-one years.

Prof Olin H Landreth, emeritus professor of engineering in Union College, Schenectady, New York, known for his work in engineering administration and sanitary engineering, on Nov 5, aged seventy-nine years.

## News and Views.

### Isolation of Vitamin A.

FOLLOWING closely on the announcement of the probable preparation of vitamin D by several independent workers (NATURE, Jan 9, p 50), come two announcements of the isolation of a substance which *prima facie* appears to be the long-sought vitamin A. In a paper published in the issue of *Helvetica Chimica Acta* for December 1931, Prof P Karrer, of the University of Zurich, together with R Morf and K Schopp, describes the isolation and purification from the unsaponifiable fraction of the liver oil of the skipper (*Scomberox saurus*) of an alcohol having the formula  $C_{20}H_{30}O$  or  $C_{22}H_{32}O$ , optically inactive, and possessing the molecular weight 300-320. Esters of acetic and *p*-nitrobenzoic acid were prepared, and the alcohol gave geronic acid on oxidation with ozone. The same substance was obtained by a special method from the liver oil of the halibut (*Hippoglossus hippoglossus*). In an address on "Recent Progress in the Chemical Study of Vitamins", given to the London Section of the Society of Chemical Industry on Jan 4, Prof J C Drummond stated that he, in collaboration with Prof I M Heilbron and Dr R A Morton, had succeeded in isolating, by a process of fractional distillation, a very potent fraction from the unsaponifiable residue of the liver oil of the halibut. The substance is a heavy, viscid oil of a slightly yellow colour, it is an alcohol, its formula is probably  $C_{20}H_{30}O$ , and its vitamin potency is of the same order as that of the recently discovered 'calciferol'. Sufficient work has

not yet been done to enable us to say that the substance is pure vitamin A, but it seems very probable that its purity is approximately ninety per cent.

### Ouabain

OUABAIN,  $C_{30}H_{46}O_{12}$ , a crystalline glucoside occurring in the seeds of *Strophanthus gratus* and in the wood of various *Acocanthera* species, was first isolated from *Acocanthera Schumperi* by Arnaud in 1888 and named ouabain, from ouabaic, an arrow poison. It is described in the German Pharmacopoeia (1926) and is included in the United States Pharmacopoeia (1926) for use as a standard for the biological control of preparations of digitalis and strophanthus. It is particularly suited for use as a standard substance, since it is easily purified and the purity is readily ascertained by the ordinary methods of chemical analysis, so that the standard is easily reproducible. Ouabain for use as a biological standard is distributed by the Bureau of Standards in the United States, and has been recommended for use by the League of Nations Health Organisation. As a pure substance it offers decided advantages, and may eventually replace the by no means uniform strophanthin of commerce, which consists of a mixture of glucosides derived from *Strophanthus Kombé*, probably in many cases contaminated with other species not readily distinguishable. Ouabain has not hitherto been readily available commercially, but it has been prepared for a number of years past in the experimental laboratories of Messrs Burroughs

Wellcome and Co for use in the associated research institutions. It has now been put on sale for research purposes and for use in clinical medicine.

#### New Biological Station in Bermuda

A new biological station has been established at Shore Hills, St George's, West, Bermuda. The site for the station and an annual grant for a period of ten years have been provided by the Government of Bermuda, while the Rockefeller Foundation has made a grant of £50,000 for the building and equipment. The station is under the management of an international board of trustees composed of leading biologists of the United States, with representatives of Great Britain and Canada. The president is Prof E G Conklin, and amongst the executive committee and officers are Profs E L Mark, E V Cowdry, C B Davenport, and R G Harrison, and Dr A G Huntsman, the Canadian representative. The two trustees representing Great Britain are Prof J H Ashworth and Dr E J Allen. The station consists of a large building, beautifully situated, with convenient access to the open sea. There is accommodation for a large number of research workers, and every facility will be provided for all kinds of biological work. Dr J F G Wheeler, who, after a training in marine research at the Plymouth Marine Biological Laboratory, became a naturalist on the *Discovery* Expedition and has published important work on whales, has been appointed director, and is now in Bermuda. According to a telegram from the *Times* correspondent in Bermuda, dated Jan 6, Sir Thomas Cubitt, Governor of the Colony, has now formally opened the station. It is to be hoped that many English biologists will take advantage of the unique opportunities which the station offers for research.

#### Association of British Zoologists

A WELL-ATTENDED meeting of British zoologists was held by the Association in the rooms of the Zoological Society of London on Jan 9, with Sir Peter Chalmers Mitchell in the chair. After two papers of technical interest, Mr J T Saunders reported on the institution, at Wray Castle, Windermere, of the laboratory of the Fresh Water Biological Association of the British Empire, and invited visiting naturalists to make use of its facilities for research. Prof E W MacBride pointed out the extreme importance of such research for the purpose of guiding legislation and departmental action on river pollution. Lieut-Col R B Seymour Sewell gave an account of the origin and history of the Zoological Survey of India, and Mr G C Robson urged the need of a comprehensive survey of the fauna of the British Isles. The Council's action in protesting against the curtailment of staff in the Zoological Survey of India was warmly approved by the Association. The Association welcomed the progress made by the Wray Castle laboratory, and agreed with the views expressed of the national and imperial importance of fresh water research, and the immediate need of further help, financial and technical. The meeting requested the Council to examine practical means to be adopted as to the survey of British fauna.

#### Exhibition of Scientific Instruments and Apparatus.

THE catalogue of the twenty-second Annual Exhibition of Scientific Instruments and Apparatus, held at the Imperial College, South Kensington, on Jan 5-7 by the Physical and Optical Societies, is an illustrated octavo volume of 160 pages and constitutes a valuable record of the position of scientific and technical instrument making in Great Britain at the present time. Although the number of firms exhibiting was slightly less than last year, the space required for their exhibits was greater, and an additional hall on the lower ground floor of the College was utilised. The circulation of the catalogue a few days before the exhibition opened was of great assistance to those at a distance who wished to purchase apparatus, as it allowed them to see which firms make the apparatus and which stands it was necessary to visit in order to compare their productions. Apparatus not previously exhibited was indicated as usual in the catalogue by an asterisk, but there appears at present to be no sign indicating when new apparatus involves the application of a principle not previously used in that type of apparatus, although there was a number of exhibits to which such a sign might have been attached. The catalogue shows a tendency, which we think should be encouraged, for makers of apparatus to give sectional views and diagrams of electrical connexions instead of pictures of the outsides of the cases containing the apparatus. Present-day purchasers are more likely to be influenced by internal arrangements than by outside appearances. As the exhibits of the firms are given in alphabetical order in the catalogues and the numbering of the stands depends not on the name of the firm but on their position in the exhibition hall, it would save the time of a visitor at a stand, who wishes to turn up in the catalogue the firm exhibiting, if, when the description of the exhibit extends to several pages, the name of the firm appeared either at the head or in the margin of each page.

#### Exhibition of Electrical Measuring Instruments

AN article by R W Paul, published in the November issue of the *Journal of Scientific Instruments*, is of general interest, as it will help to keep green the memory of the Faraday Centenary Exhibition at the Albert Hall, London, in 1931. He gives excellent descriptions of many of the instruments shown, which illustrate the gradual development of accuracy and quickness in measurement. Ammeters were first made having needles of soft iron polarised by a powerful magnet and having a deflecting coil closely adjacent. In 1881, Ayrton and Perry designed such instruments, the scales being graduated in degrees, which were converted to amperes by the application of a constant. They were the first to use the term 'ammeter' instead of amperemeter. It is interesting to remember that Silvanus Thompson strongly discouraged the use of this word, and asked sarcastically why they did not also use the word 'vometer' for voltmeter. The Director of the Science Museum has arranged that much of the apparatus shown at the Exhibition will be displayed at the museum from February until May 1932.

### Control and Operation of Cable Telegraphy

THE success of short-wave radio telegraph 'links' during recent years is well known to have led to the merging of the most important of the cable and radio companies. In addition, the rapid strides made in radio telegraphy and in international telephony have produced the impression that submarine cable telegraphy is now of little value. In a paper read to the Institution of Electrical Engineers on Jan. 7 by H. Kingsbury and R. A. Goodman on cable telegraphy, it is stated that there are no signs of the supersession of transoceanic cable telegraphy by radio, due to economic or other reasons. The growth of cable communications between the countries of Europe and the rest of the world is both steady and satisfactory.

UNFORTUNATELY, it has always been the general policy of the European States to retain not only the control but also the actual operation of their telephone systems. Hence at the international meetings the majority of the delegates are merely representative of the interests of their governments. The immediate revenue accruing to the State rather than the development of a first-class foreign telegraph service is their main consideration. It is therefore difficult to introduce reforms, no matter how desirable they seem to the engineers of private companies. Cable companies could easily compete with the direct radio beam, provided that the companies had control of all stations and that land lines were available and properly maintained. Many minutes are added to the transmission time of a message by the mere handing over of traffic from a company to a government system. For example, a preferred rate message from San Francisco to Copenhagen handed in over the counter in the ordinary way occupies about fifteen minutes from the time it passes out of the sender's sight until it is in the hands of the addressee. On the other hand, a sender offering a short telegraph message by telephone in New York for London is reasonably certain of delivery in two minutes from the moment of completing dictation of the message in New York.

### Weather of 1931.

In a pamphlet entitled "Notes on the Weather of 1931", issued by the Meteorological Office (Air Ministry), the topsy-turvy character of last year's weather is clearly brought out. New 'records' for cold were set up in March and October, months that are only on the fringe of winter and sometimes provide summer warmth. On March 3 temperature fell to 1° F. at Braemar, and on March 10 to 5° F. at Rickmansworth. On the latter date temperature failed to rise above 30° during the day in many places in south-east England. The night frosts of the last week of October were in some parts of England the most severe ever recorded in that month. There was a pronounced tendency for the worst weather in the south-east of England to be reserved for week-ends and public holidays, and the August holidays provided some days that were much colder than those experienced at Christmas. The gale in the English Channel on Aug. 24 would have been noteworthy had

it occurred in mid-winter. No temperature within three degrees of the reading of 61° that was recorded at Aberdeen on Christmas Eve has ever been known there in December for at least sixty years. Mention should be made also of the very rare event of a tornado of the American type, on June 14, at Birmingham. Although not to be compared with the worst tornadoes experienced in America, this storm was violent enough for roofs to be stripped, and there was loss of life. The zone of destruction was, fortunately, a characteristically narrow one, varying from 200 yards to 800 yards. The year must be regarded meteorologically as one of the most eventful known since the Meteorological Office was inaugurated nearly eighty years ago.

### Prehistoric Stock of South Africa

At a meeting of the Royal Anthropological Institute (Section of Human Biology) on Jan. 8, Sir Arthur Keith exhibited a series of human skulls from the Matje River Rock Shelter, a newly discovered prehistoric site in the Zitzikamma District, on the coast of the Cape Province. The deposits in this rock-shelter, amounting to 21 feet in depth, were excavated by Prof. T. F. Dreyer, of Grey University College, Bloemfontein. The rock-shelter was first inhabited during the age of the 'Mossel Bay' culture, which is usually equated with one of the later palæolithic cultures of Europe, and this culture was richly represented during the formation of the deeper strata, amounting in depth to 14 feet. All the remains from the Mossel Bay strata manifest racial traits, which were first revealed by the discovery of the large-brained Boskop skull in 1913. Three of the skulls from the deepest Mossel Bay strata have peculiar features of the forehead, the frontal bones appear compressed from side to side, with a high median keel. This malformation, known as trigonocephaly, occurs occasionally in modern races. A tendency to trigonism is not uncommon among Bushmen and Hottentots, who may be regarded as descendants of the prehistoric stock of South Africa. Sir Arthur Keith added that South Africa was the home of the most remarkable of all prehistoric peoples known to us, a people or stock tending to produce individuals with brains of remarkable dimensions and with a tendency for infantile and juvenile characters to persist into adult life, a tendency which Prof. M. R. Drennan has termed 'pedomorphism'. Although remains of Bushmen have been found so far north as Lake Nyassa and Boskop remains in Northern Rhodesia, all the evidence at present points to South Africa as the evolutionary home of this prehistoric pedomorphic race.

### Prehistoric Gold Ornaments from Cornwall.

Two torques and six penannular armlets have been found by a farm labourer in a bank of earth on Amalveor Farm, in Towednack, near St. Ives, Cornwall. According to the *Times* for Jan. 2, one of the torques consists of three strips of twisted metal, the other, a single twisted coil, is of considerable length, its circle being 13 in. in diameter, and, being flexible,

it may have been worn twined several times round the neck or waist. Both have the ends bent back to form the familiar interlocking hook. Of the armlets four are simple metal rods, the remaining two are heavier, one being hexagonal and the other lozenge-shaped in section. The find is assigned to the middle or late bronze age, but it is to be noted that the simple armlets do not show the thickening of the wire at the ends characteristic of the developed type of armlet, which, in the British late bronze age, expanded into the cup-shaped terminals.

• THE number, character, and distribution of finds of prehistoric gold ornaments in Cornwall, of which that of a lunula, or crescent-shaped gold neck ornament, associated with a flat axe found at Harlyn Bay is the best known, would suggest that intercourse with Ireland, the undoubted source of these ornaments, began early, possibly at the very beginning of the bronze age, and was extensive. Not only did Cornwall provide tin, in which Ireland was poor, but it served as a stage in the voyage to Brittany and Iberia. Close intercourse between Ireland and Cornwall lasted well into Christian times, as is shown by the legends of the Cornish saints, though their many obviously mythical details point to a much earlier tradition. It is to be hoped that lack of funds will not stand in the way of the proposed excavation of the site on which this latest find was made. If it should prove a habitation site, as is conjectured, it should furnish much needed evidence corroborative of the dating of Cornish gold ornaments.

#### American Patent Law System.

UNDER the auspices of Science Service, Dr. E. J. Prindle gave, on Nov. 13, a radio talk on the American patent law system. He pointed out how backward agriculture and manufacturing were prior to the introduction of the patent system, which gave the inventor the exclusive right for seventeen years to make, use, and sell his invention. So great is the transformation made by the introduction of machinery, that in garnering wheat crops one man can, by its use, do the work formerly requiring ten men. Only one man is now required for every 250 acres. The making of agricultural machinery is a very large industry. The expense of developing a single invention often runs into hundreds of pounds, and sometimes, as in the case of the Curtis steam turbine, into hundreds of thousands of pounds. Without the possibility of recovering this sum and making a profit on the invention, neither individuals nor companies can afford to make and perfect inventions. Without the patent law, Edison could not have accomplished his great work which has benefited humanity. In connexion with electric lighting alone, Edison took out 375 patents. As a patent for an invention gives a monopoly, some think that it is therefore harmful, as many monopolies undoubtedly are. But a patent only gives an inventor a monopoly of that which he creates, it takes nothing from the public, and at the end of seventeen years the public receives the invention free. In normal times, the patent system has greatly increased the field of employment.

#### Hawks as Decoys.

MARTIAL's epigram on the hawk (Book 14, 216) has been taken as an indication that falconry was practised by the classical ancients, but as the hawk here deceives (*decipit*) the birds, it would seem rather as if it were used, like an owl, as a decoy to entrap birds coming to mob it, and in the *Field* for Dec. 26, 1931, Col. Nawab Malik Sir Umar Hayat Khan, in writing on falconry, indicates a similar practice in modern India, for he says that if a sparrow-hawk be kept under a net or in a cage and nooses made around, and the receptacle put where 'seven sisters' are common, these birds (the common Indian babbler *Turdoides tericolor*) can be caught by the dozen. Being weak flyers, they are particularly likely to be attacked by hawks, but being also sociable and strong in beak and claws, they often succeed in rescuing the bird attacked, so that the hawk is an enemy with which they contend on more or less equal terms. The use of the captive hawk as a decoy, however, is no more falconry than is the employment of wild hawks in fowling by bribing them to 'wait on' and make birds lie, a practice also followed in classical times and in India and Argentina in our day, when the former country is still the stronghold of the perfected art.

#### Statistics of Cancer in East London.

THE Ministry of Health has issued a report by Dr. Janet Forber (*née* Lane-Claypon) dealing with incurable cases of cancer in east London (*Reps. on Pub. Health and Med. Subjects*, No. 66, H.M. Stationery Office, 1s. net). There appears to be no shortage of medical and nursing care and hospital accommodation for these patients. The sample of 1983 cases investigated brings out (as other investigations have done) a contrast in sex incidence of the disease, namely, the great preponderance of cancer of the lip, tongue, mouth, pharynx, and larynx in the male, and cancer of the reproductive organs in the female. The mean age at death is low for fatal cancer of the uterus, ovary, and, in both sexes, the lung and pleura, and high for fatal cancer of the skin and prostate. The mean duration of in-patient care for those who seek hospital treatment is only 2.28 months, being less than one month for 46 per cent, suggesting that the terminal and troublesome stage of fatal cancer is, happily, of short duration.

#### Researches in Chemical Engineering

WE have received the *Proceedings of the Chemical Engineering Group, Society of Chemical Industry*, vols. 11 and 12, 1929 and 1930 (in one volume). This contains a number of valuable papers, dealing with such subjects as surface energy, flotation, water treatment, alloy steels, gas and electric heating furnaces, and welding. The standard of the papers is high, and they are usually followed by interesting discussions. The *Transactions of the Institution of Chemical Engineers*, vol. 8, 1930, has also been received, and contains important papers on various subjects related to chemical engineering, such as cellulose products, crystallisation, high pressure reactions, tannery waste, wood pulp, pulverised fuel, and the recovery of metals from waste materials. Both these volumes are very

well printed and illustrated, and form valuable contributions to the literature of applied chemistry and engineering

#### U.S. Bureau of Standards

*Miscellaneous Publication* No 131 of the Bureau of Standards, Washington, constitutes the Annual Report of the Bureau for the year ending June 1931. Notwithstanding the decrease in industrial activity in the United States, the demands on the Bureau for its services were greater than in the previous year, and the working costs were 2,600,000 dollars, an increase of 5 per cent on last year. The staff number nearly 12,000, and the salaries 710,000 dollars. A new hydraulic laboratory, capable of dealing with 300 cubic feet per second, and two new radio stations have been built, and a new administrative building and a high voltage laboratory are in contemplation.

#### Announcements

THE gold medal of the Royal Astronomical Society has been awarded to Dr Robert Grant Aitken, director of the Lick Observatory, Mt Hamilton, California, for his work on double stars.

SIR ROY LISTER ROBINSON, technical commissioner in the Forestry Commission, has been appointed chairman of the Commission, in succession to Sir John Stirling-Maxwell, who is retiring on March 25 next.

THE following appointments in the Colonial agricultural services have recently been made by the Secretary of State for the Colonies. Mr A. J. Findlay, deputy director of agriculture, Nigeria, to be director of agriculture, Zanzibar, Mr T. Y. Watson, to be agricultural officer, Kenya.

THE Melchett Medal for the year 1931 of the Institute of Fuel has been awarded to Prof William A. Bone, professor of chemical technology in the Imperial College of Science and Technology, London. This medal was founded in 1930 by the late Lord Melchett, and is given for original research or professional, administrative, or constructive work involving the scientific preparation or use of fuel, which has recently been made available to the community. The first award was to Dr Kurt Rummell, of Dusseldorf.

A JOINT committee of the British Empire Cancer Campaign and the Mount Vernon Hospital has appointed Dr A. E. Barclay, lecturer in medical radiology and electrology in the University of Cambridge, to the Radiological Research Fellowship founded by Sir William Morris at the Mount Vernon Hospital.

It is announced in *Science* that the Henry Draper Medal of the U.S. National Academy of Sciences has been awarded to Dr Annie J. Cannon, of Harvard College Observatory, for her work on the classification of stellar spectra. This medal is given "for notable investigations in astronomical physics." Dr Cannon is the first woman to receive a medal from the National Academy of Sciences. The Agassiz Medal of the

Academy, given for contributions to oceanography, has been awarded to Prof H. B. Bigelow, director of the Oceanographic Institution at Woods Hole.

THE course of open lectures in anthropology at the Royal Anthropological Institute for the second half of the session 1931-32 is announced. The course has been arranged in co-operation with the School of Oriental Studies, and will deal with African life and customs. The list of subjects and lectures is as follows: Jan 20, F. H. Melland, on natural resources of Africa; Jan 27, Prof C. G. Seligman, on races of Africa; Feb 3, C. W. Hobley, on the development of native education in Kenya; Feb 16, Capt R. S. Rattray, on Hausa poetry; March 2, Rev. E. W. Smith, on the place of folk-tales in African life; March 9, H. J. Braunscholtz, on the craft of the African potter; March 16, J. H. Driberg, on African systems of education. The lectures begin at 5 P.M. on each day, and admission is free and without ticket.

A LIST (C 1931) of some 1586 works relating to science, including publications of the Geological Survey of Great Britain, Smithsonian Miscellaneous Collections, and publishers' remainders, has been issued by Messrs Wheldon and Wesley, Ltd, 2 Arthur Street, W.C.2.

THE latest catalogue of Messrs Bernard Quaritch, Ltd, 11 Grafton Street, W.1 (No 452), should be of much interest and service to librarians and others, giving as it does particulars of some 1300 works relating to science, mainly in the form of periodical literature, transactions of learned societies, and records of voyages of exploration. Many of the entries have valuable bibliographic notes appended.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned: A demonstrator in pathology and bacteriology at the Welsh National School of Medicine—The Acting Secretary, University Registry, Cathays Park, Cardiff (Jan 21). A senior chemistry master at Emanuel School, Wandsworth Common—The Headmaster, Emanuel School, Wandsworth Common, S.W.11 (Jan 23). A temporary senior technical assistant in an Admiralty establishment near London, with experience in the design of light precision machinery and small accurate gearing—The Secretary of the Admiralty, C.E. Branch, Admiralty, Whitehall, S.W.1 (Jan 29). An expert under the Egyptian Government, for the study of sugar-cane pests and methods of control and to organise the application of control measures, also for the study and carrying out of research work on the varieties of sugar-cane most adapted to local conditions, methods of cultivation, and other factors tending to improve sugar culture—The Minister of Agriculture, Cairo (Feb 15). A head of the mathematics department of the Woolwich Polytechnic—The Principal, Woolwich Polytechnic, Woolwich, S.E.18 (Feb 17). A director of the Indian Institute of Science, Bangalore—The Selection Committee, Directorship Indian Institute of Science, Bangalore, c/o The Universities Bureau, 88A Gower Street, W.C.1, (before end of April).

## Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

## Velocities of the Spiral Nebulae.

THE extraordinary velocities of recession which are derived from the shift toward the red of the spectral lines of remote galaxies have led to much scepticism of the interpretation of this shift as a Doppler effect, and this scepticism is enhanced when it is learned that the velocities are proportional to the distances of the galaxies. No other interpretation in terms of ether waves seems to be satisfactory, but there is an interpretation in terms of light quanta, or photons, that is much less disturbing.

The energy of a photon is  $\epsilon = h\nu$ , where  $h$  is Planck's constant and  $\nu$  is the frequency. If one supposes that there is a leakage of energy from the photon in its long journey of millions of years, due perhaps to an inherent instability in the photon, or, possibly, to collisions with other photons, it is evident that the frequency declines with the energy, and the lines of the spectrum are shifted toward the red.

For the Doppler effect  $\nu = \nu_0(1 - v/c)$ , where  $v$  is the velocity of recession and  $c$  is the velocity of light. Hubble and Humason<sup>1</sup> find, from observation of these distant objects, the relation

$$v \text{ (in km per sec)} = \frac{x \text{ (in parsecs)}}{1790},$$

so that

$$\frac{v}{c} = \frac{x \text{ (in parsecs)}}{3 \times 1790 \times 10^5} = \beta x$$

If, instead of this linear relationship between velocity and distance, one takes  $v/c = (1 - e^{-\beta x})$ —and the two hypotheses are indistinguishable on the basis of the observational data—then the relation between frequency and distance due to Doppler effect is  $\nu = \nu_0 e^{-\beta x}$ .

On the other hand, if one supposes that the percentage loss of energy from the photon per unit distance is constant, one has

$$\frac{1}{\epsilon} \frac{d\epsilon}{dx} = -a,$$

where  $a$  is some constant. Consequently,  $\epsilon = \epsilon_0 e^{-ax}$ , or, on dividing through by Planck's constant,  $\nu = \nu_0 e^{-ax}$ . That is, the assumed tendency of the energy of the photon to evaporate in its long journey through space leads to a law of frequency which is indistinguishable in form from the law of Doppler effect as given by Hubble and Humason.

On the basis of energy leakage and the observed shift of the spectral lines, a light quantum loses one per cent of its energy in 5,400,000 parsecs, or 17,600,000 years. It requires 372,000,000 parsecs, or 1,210,000,000 years, for one-half of its energy to escape. Such an interpretation of the extraordinary shifts that are observed will be more acceptable to many than an interpretation which makes our galaxy a centre from which all others are fleeing with speeds that are proportional to the distances.

If the energy which has evaporated from the photon continues to exist as radiant energy, there should exist an abundance of radiation of very low frequency, and there is at present no evidence of such radiation. Another possibility, however, is that it disappears into the fine structure of space and reappears eventu-

ally in the structure of the atom. The process by which this is accomplished, however, lies far outside the range of our experience, and until we know much more about the atom than we do at present, it is useless to speculate about it.

W D MACMILLAN

University of Chicago,

## Oxygen and Everest.

MR ODELL's interesting letter<sup>1</sup> re-emphasises conclusions drawn from the Everest expeditions as to the value of oxygen breathing apparatus and upholds the importance of acclimatisation. He states that acclimatisation at 27,000-28,000 feet should be aimed at, and then oxygen used for the last 1000 feet of ascent. As it takes weeks for the party to reach 27,000 feet, experiments in pressure chambers conducted on normal men for a few hours' duration are of no significance. We know, however, that natives do not go and live in the summer months above 18,000 feet, and the question arises whether it is the altitude or the extent of the pastures which sets this limit.

It was on account of this that Dr Argyll Campbell carried out many experiments with animals while I was in charge of the Department of Applied Physiology at the National Institute of Medical Research. He used monkeys, cats, rabbits, guinea-pigs, rats, and mice, enclosing these animals almost continuously in chambers for many weeks, either the oxygen partial pressure, or the barometric pressure being lowered gradually to resemble the conditions on the mountains. In the latter case, use was made of a chamber at the works of Messrs Siebe Gorman. His results have been published and clearly show that at 20,000-29,000 feet the oxygen tension in the tissues is not kept at normal, but is markedly subnormal, further, there result pathological changes, particularly in the heart, liver, and brain. Also, he found that breathing oxygen at normal pressure for one hour daily did not help these animals materially.

Thus in the so-called acclimatisation at these great altitudes the members of the expeditions will be deteriorating continuously, that they did so in the past expeditions is proved not only by the fact that climbing became most difficult, but also that they all lost weight and appetite. The climbers who persevered at 28,000 feet or above all came to grief.

Another expedition of the same type is likely to end similarly unless other precautions are taken. Dr Campbell found that out of more than a hundred healthy animals only about ten could tolerate the low oxygen partial pressure which pertains at 29,000 feet for any length of time. A few animals survived for eight days—a record—under this pressure, and recovered their health again when put under normal conditions.

It is obviously very difficult to pick men able to tolerate such a low oxygen pressure for such a prolonged period as is necessary on the mountain. The climbing party should be increased in numbers, and thus the chance of one of them carrying on after 28,000 feet, with or without the use of oxygen breathing apparatus, will be increased. All the evidence from the expeditions and from these experiments on animals leads to one conclusion, namely, above 28,000 feet deterioration is rapid and excessive, and no acclimatisation prevents this. If the climbers were continuously supplied with oxygen at normal pressure they could, of course, proceed straight up to the

summit. Some day, perhaps, a liquid oxygen apparatus will be established at the 18,000 feet level and Everest thereby conquered in safety.

LEONARD HILL

Nicholls Wood,  
Chalfont St Peter

<sup>1</sup> NATURE, 128, 1037, Dec 19, 1931

WITH most of what Mr N. E. Odell says,<sup>1</sup> in commenting upon my paper "Oxygen and Everest", I am entirely in agreement. There are one or two points, however, on which I would like to reply.

Though Mr Odell does not actually suggest it, it might possibly appear that I had cast doubt on the possibility of acclimatisation to 29,000 feet. There is, of course, no reason to doubt the possibility, on lines either theoretical or practical. There is, however, an element of doubt as to whether so high a degree of acclimatisation can be obtained in the time available, owing certainly to the slowness of the process and possibly to the onset of altitude deterioration.

I agree that "there is nothing to warrant Dr. Greene's supposition that their [Mallory and Irvine's] failure to return was due to a breakdown in the oxygen apparatus". I have never supposed such a thing. It has never even occurred to me. I did, however, suggest as a possibility that their *lateness* might be due to this cause. This is a very different matter, and it remains a possibility, but not a supposition.

Many climbers certainly believe that Everest should be climbed without "such artificial aids as may reduce a sport to a mere laboratory experiment". Others believe that such aids may raise a mere sport to the dignity of a laboratory experiment. But I do not follow the sentence with which Mr Odell follows up this appeal to all that is best in British sport. No one wants to repeat the steel chamber experiment he has mentioned. Some even wonder why it was ever done. But we do want to know by direct experiment whether oxygen is of use to an acclimatised man and we do want to know whether a man can acclimatise fast enough to climb Everest in the time available. Where, as Mr Odell says, can these things be better studied than on Everest?

I made no mention of my ammonium chloride experiments because they are still in their infancy and any conclusions based upon them would be premature and unsound.

Through my carelessness, two misprints appeared in my article. In paragraph 4 'exponents' should read 'opponents', and in the last paragraph 'mid' should read 'wind'.

#### L-Discontinuities in X-Ray Absorption.

By definition, the absorption coefficient is the factor of proportionality of absorption in an infinitely thin layer. The atomic absorption coefficient, then, is the factor of proportionality for a very small number of atoms. This factor, therefore, can be said to be a measure of the probability of absorption for each photon passing the atom.

It is also obvious from Kossel's atomic model that if an electron has been removed from a certain level by an absorption process, this must be accompanied by an emission process corresponding to an electronic transition into the vacant position. Therefore the absorption processes of the highest excited level must be as frequent as the emission processes from this level. The coefficient of absorption therefore must be

a measure not only of the probability of absorption but also of the probability of emission.

We shall now consider the special case when the frequency of the absorbed radiation has reached the  $L_m$ - and  $L_n$ -absorption limits but not  $L_i$ . The excited levels are then  $L_{22}$  and  $L_{21}$  and, of course, lower levels. Now the unusually well-established rule of Burger and Dorgelo can be used. It is possible to arrange the lines, originating from those levels, in doublets or triplets in such a way that the ratio of intensity of the components is 1.2, according to the rule mentioned. For example,  $\beta_1/(\alpha_1 + \alpha_2) = 1.2$ ,  $\gamma_1/(\beta_2 + \beta_{15}) = 1.2$ ,  $\eta/l = 1.2$ . Generally 1.2 is the ratio of the numbers of quanta emitted from the two levels. Therefore the numbers of absorption processes must have the same proportions. We then conclude that when the frequency of the absorbed radiation exceeds the  $L_n$ -absorption limit, the probability of absorption will increase with 50 per cent of the probability of absorption in the  $L_{22}$ -level. If we take in account also the  $M$ -absorption, we can give the expression

$dL_n = \frac{1.5a + m}{a + m}$ , where  $m$  is proportional to the absorption in the  $M + N + \dots$  levels and  $a$  to the  $L_{22}$ -absorption. For elements with low atomic number,  $m$  will be negligible and therefore  $dL_n = 1.50$ . The only experimentally determined values available are Ag(47)  $dL_n = 1.47$ , Pt(78)  $dL_n = 1.37$ , Au(79)  $dL_n = 1.38$ , Hg(80)  $dL_n = 1.39$ . They also confirm that  $dL_n > 1.50$  with decreasing atomic number.

E. Jonsson calculates the absorption using formulæ such as  $dL_n = \frac{E_{L_n}}{E_{L_{22}}}$ , where  $E$  represents the  $\nu/R$  value

of the designated absorption limit. In the case of silver, for example, we get in this way  $dL_n = 1.05$ . Although the formula holds for the  $K$  and the total  $L$  discontinuity, in the case of  $dL_n$  it has no justification.

It is not possible to calculate in the same way as  $dL_n$  the other  $L$ -discontinuities. The lines of  $L_n$ , for example, cannot be arranged in groups with lines from the other  $L$ -levels, the components having a constant ratio of intensity. One would suppose that the experimentally found sum of the intensities of all the lines originating from a certain level would give a value of the probability of absorption in this level. The agreement is not good, however. In the case of silver we calculate  $dL_n = 1.10$ , but experimentally it is found to be  $dL_n = 1.25$ .

On the basis of the new quantum mechanics, Wentzel calculated the relative intensities of a number of lines in the  $L$ -series. In several cases his values are considerably higher than the observed data. Wentzel suggests that the failure may depend on 'non-radiating transitions' or inner absorption, that is, the photons emitted are partially reabsorbed in the lower levels before leaving the atoms. But such emitted quanta must also be included in the calculated rate of emission from different levels. If Wentzel's explanation of the difference between the calculated and observed values is quantitatively correct, we can best make the correction for the inner absorption by using his calculated values. This gives  $dL_n = \frac{1.79a + m}{1.46a + m}$ ,

giving 1.23 as the upper limit to which the  $dL$ -discontinuity tends with decreasing atomic number. In fact the observed values are Ag(47)  $dL_n = 1.25$ , Pt(78)  $dL_n = 1.25$ , Au(79)  $dL_n = 1.25$ , Hg(80)  $dL_n = 1.18$ . Perhaps this can be said to provide the experimental agreement to Wentzel's calculations not given by the directly observed intensities of the emitted lines.

## Atomic Moments of some Metals

M. CH. SADRON a fait, dans mon laboratoire, une étude de l'aimantation à saturation des solutions solides des métaux dans le nickel ou dans le cobalt, dans les champs intenses et aux basses températures. Il a trouvé ainsi que de nombreux métaux possèdent des moments ferromagnétiques et a déterminé leur grandeur.

Si l'on ajoute au nickel un métal M, le moment atomique moyen est représenté par la droite AC (Fig 1), d'après la loi des mélanges. Le commencement AB de cette droite est observable et son prolongement donne en C le moment du métal M.

On trouve ainsi pour le palladium et pour le platine le moment de 3 magnétons (1 magnéton = 1126.5) qui est aussi celui du nickel. Donc les éléments situés, comme le nickel, le palladium et le platine, dans une même colonne du système périodique ont le même moment.

Les solutions du manganèse dans le nickel ont donné +15 magnétons pour manganèse, par contre celles du manganèse dans le cobalt ont donné -15 magnétons. Dans le nickel, le moment 15 du manganèse se place

FIG 1

FIG 2

parallèlement, dans le cobalt antiparallèlement au moment du solvant. L'orientation antiparallèle est la plus fréquente, c'est celle du cuivre, du chrome dans le nickel. Mais aussi bien que l'orientation parallèle, elle permet la détermination du moment. On trouve ainsi pour le chrome, le molybdène, le tungstène, qui sont situés dans la même colonne, le même moment de 19 magnétons.

La détermination des moments de la ligne horizontale du fer a été faite soit sur les éléments eux-mêmes, soit en les remplaçant par d'autres éléments de leur colonne. Ainsi le scandium a été remplacé par l'aluminium, etc.

Les résultats sont représentés en trait plein dans la Fig 2 (La ligne interrompue est la courbe de Cabrera du moment des ions).

Les moments ferromagnétiques se placent sur deux droites se rencontrant au vanadium, qui a le moment le plus élevé, égal à 23 magnétons. La pente de la partie ascendante est voisine de 5 magnétons, ou un magnéton de Bohr, celle de la partie descendante est exactement égale à 4 magnétons.

## Diamagnetism of Liquid Mixtures.

CRITICISMS of our magnetic susceptibility measurements of mixtures of acetone and chloroform<sup>1</sup> have been made by Ranganadham,<sup>2</sup> van Aubel,<sup>3</sup> Buchner,<sup>4</sup> and Ramachandra Rao and Sivaramakrishnan.<sup>5</sup> We have therefore repeated the susceptibility measurements of this series of liquids by the Gouy method, using a magnet with a field strength of about 3300 gauss. The apparatus not being available in this laboratory, Dr S. Sugden, to whom we wish to express our thanks, kindly permitted us to make use of his apparatus at Birkbeck College. With this particular apparatus values of the susceptibility can be obtained which are accurate to within  $\pm 0.02 \times 10^{-6}$ .

The results of the new set of measurements show that we are decidedly in error, whilst our critics are right in respect of the sign of the susceptibility of mixtures of acetone and chloroform and of the compound formed by these two substances. Our critics, however, are not in agreement as to the amount by which the susceptibility of mixtures of acetone and chloroform diverges from the simple mixture rule. Dr Buchner finds that the maximum deviation is 2 per cent. Messrs Ramachandra Rao and Sivaramakrishnan find no deviation from the mixture rule, and Mr Ranganadham finds a maximum deviation of 3 per cent.

Dr Buchner points out that we give the density of dimethyltrichloromethyl carbinol as 0.66, this figure is due to an error of transcription and should have read 1.66. Freshly sublimed material has been prepared and this specimen, which is white, has the value  $d_4^{25} = 1.49$ . The following mass susceptibilities have been obtained: acetone -  $0.60 \times 10^{-6}$ , chloroform -  $0.51 \times 10^{-6}$ , and dimethyltrichloromethyl carbinol -  $0.59 \times 10^{-6}$ . The maximum deviation of the susceptibilities of the mixtures from the straight line is not more than 5 per cent, and it lies at the equimolecular mixture.

The values given above agree reasonably well with those given by Dr Buchner, and our new value for acetone is now in agreement with the figure given by Pascal.

So far as we are able to judge, the error in our measurements has arisen through a mechanical defect in the arrangement for moving the magnet from one fixed position to the other, thus leading to an inaccurate deviation being recorded. From our laboratory notes it is fairly clear when the defect occurred, and therefore we propose to remeasure, and correct where necessary, the whole of our magnetic measurements, using a new apparatus which we are installing.

at the moment and which will be capable of furnishing a very much stronger field

Since the above was written, Dr J Farquharson has published a letter<sup>8</sup> giving results which are in complete agreement with those above

### Oysters in Law.

THE European oyster, or flat oyster, *Ostrea edulis*, Linn, occurs in many places off the Atlantic and Mediterranean coasts of Europe. In all these localities this oyster in the warmer periods of the year reproduces its kind by extruding eggs from the body, but it retains and incubates these eggs within its shell-spaces until the resulting larvæ have developed organs which permit an independent free-swimming life. The incubation of eggs to the larval stage is thus a common character of English, Irish, Scotch, Norwegian, Danish, German, Dutch, French, and Italian flat oysters. At present all these flat larviparous oysters are regarded as belonging to one species, namely, *Ostrea edulis*, Linn, except for certain oysters occurring in the Adriatic Sea,<sup>1</sup> albeit a large number of varieties have been given special names<sup>2</sup>

It has long been recognised in England that the consumption of English native oysters during the warmer months, that is, the breeding period, is undesirable for many reasons, one important one being the danger to the consumer of infection from harmful bacteria and other noxious materials which may be passed on by oysters weakened by the process of breeding, and otherwise deleteriously affected by transport in the warm conditions usually prevailing in the breeding period.

The sale of English native oysters (*O. edulis*) for consumption during certain months of the year (usually the breeding months) has been prohibited by law since 1877,<sup>3</sup> but foreign oysters, including American (*O. virginiana*) and Portuguese (*O. angulata*) as well as foreign *O. edulis*, were exempted by that law, and remain exempted. The American and Portuguese oysters do not incubate their young, they do not spawn much in Great Britain, and may be expected normally to maintain themselves in good condition for consumption during the summer: there are therefore fewer objections to the sale of these forms for consumption in summer than apply to *O. edulis*. On the other hand, foreign *O. edulis* are in essentially the same category as English *O. edulis* with regard to their liability to weakness in the warmer months of the year, for there can now be little doubt that *O. edulis* may breed in the sea in varying percentages in any locality at any time the sea-water is maintained steadily above the level of about 58°-59° F.<sup>4 5 6</sup> Thus every objection to the sale of native, or English-grown, *O. edulis* during the breeding period on the ground of safeguarding public health is equally applicable to foreign *O. edulis*, whether these be reared in English waters or not.

Efforts have been made in the past to bring foreign flat oysters (*O. edulis*) under the same regulations as English,<sup>7</sup> but the objects have been confused by (a) the lack of recognition that foreign oysters may be of three kinds, namely, (1) American (*O. virginiana*), (2)

Portuguese (*O. angulata*), which are both non-larviparous forms, and (3) European flat larviparous oysters (*O. edulis*), which are conspecific with English natives, and (b) the desire to protect and husband the English oyster beds during the breeding season. At the present day, probably little opposition would be offered to a law prohibiting the sale of foreign *O. edulis* in the British Isles during the same period and under the same conditions as the sale of English *O. edulis* is prohibited. The present time is also highly propitious for the passage of such a law, as the economic disturbance would be slight—owing to the relative scarcity of *O. edulis*—and the Parliamentary machinery may find little difficulty in dealing with the matter.

English oyster beds, it may be observed, require nursing during the non-breeding as well as during the breeding period, according to local requirements, moreover, the variation in the length of the breeding period in different localities also renders it desirable that a measure of power should be delegated to local authorities—as in fact exists at present—to modify, within limits, any general prohibitory regulation.

The biological facts given above are presented independently as a biological duty now somewhat overdue, but there would seem to be little doubt that if the oyster merchants and others concerned could meet to discuss this problem, agreement might soon be reached resulting in the removal of an anomaly, which is possibly not very serious, but is nevertheless a haunting menace not only to public health but also to the oyster trade itself.

### Geological Sequence of Coombe Deposits at Greenhithe, Kent

A STUDY of the Geological Survey Map (Sheet IX, N E Kent, scale 6 in to 1 m) reveals four lateral valleys, now filled with Coombe Deposits of Pleistocene age, which formerly drained into the Thames. The Geological Survey has described one of these valleys as follows:

"Besides the bedded gravels and brickearths which have been laid down at various periods by the rivers, there are deposits which, although occurring in the valleys, show little sign of arrangement by running water. In many of the smaller valleys, more particularly in Kent, we find the bottom filled with an accumulation of mixed material to which the name 'Coombe Deposits' may be given. These masses have been formed by the descent of material from the sides of the valleys, and take their character from that of the deposits available at any spot: thus, in the valley starting near Bean and opening into the Thames at Greenhithe the Coombe Deposits include gravel from the High Terrace deposits, a sandy loam formed of Tertiary material and best described as brickearth—it has, indeed, been used on a small scale for brick-making—and chalk rubble. The last resembles the deposit known as 'Coombe Rock', the origin of which has been discussed by Clement Reid, and the whole assemblage has probably been formed in the same way, the period of formation appears to be that of the down-cutting between the Middle and the Low

Terraces and of the cold period at the base of the latter"<sup>1</sup>

The deposits composing the infilling of the lower part of this valley are shown by the Survey to be "Brickearth 2 to 4 feet", "Gravel with big flints 0 to 6 feet", and "Chalk Rubble 6 feet", whilst in the tramway-cutting immediately west of Cobham Terrace a section is recorded as "Brickearth 2 feet", "Gravel 4 feet", and "Chalk Rubble 8 feet"

Here, as in the lateral valley to the east,<sup>2</sup> I have found the stoneless brickearth, which rests upon the melt-water gravels of the Coombe Rock and underlies the stony loam, to contain artefacts of Upper Palaeolithic types together with calcined flints. In places the Bean-Greenhithe brickearth is calcareous and tuffaceous, when, in addition to the implements exhibiting a white porcellaneous patination, the shells of various land molluscs of temperate species have been preserved in the deposit

The researches I have undertaken within the area included on Sheet IX, N.E. Kent, 6 in to 1 m, definitely establish a break in the deposition of the Coombe Deposits, a break which occurred after the melt-waters of the Coombe Rock glaciation had subsided, but prior to the deposition of the stoneless brickearth<sup>3</sup>

In the geological sequence the Survey places the Coombe Deposits between the formation of the Middle and Low Terraces this correlation is supported on archaeological evidence in the vicinity of Belmont Castle, Grays, Essex, where the Coombe Deposits are overlain by the Upper Flood Plain gravels<sup>4</sup>

The break in the deposition of the Coombe Deposits referred to above must necessarily represent the interglacial phase coincident with the Upper Palaeolithic (Upper Mousterian, Aulignacian, and Solutrian) period

### Structure and Development of Temperature Inversions in the Atmosphere

THE present view of the development of temperature inversions in the atmosphere with a sudden decrease of humidity with increase of height as due to a general slow descent of air from higher levels,<sup>1</sup> regards the appearance of the temperature discontinuity as a condition precedent to the development of humidity discontinuity in the form of a haze or cloud layer below it. Kopp,<sup>2</sup> however, from the experience of his aeroplane flights, pointed out that after the passage of a cyclone, humidity discontinuity in the form of haze or cloud layer precedes the temperature discontinuity, the latter being probably brought into existence as a result of radiation from the haze or cloud layers. An examination of Lindeberg and Berlin kite and aeroplane ascents confirms the view that dry inversions in the free atmosphere can and do owe their origin to humidity discontinuities in the form of haze layers or cloud sheets

In a forthcoming publication, we have discussed the rôle of subsidence and radiation in the production of inversions both qualitatively and quantitatively. It has been shown that subsidence combined with turbulence up to a definite limit<sup>3</sup> cannot adequately explain the development and maintenance of dry horizontal inversions in anticyclonic weather, but that radiation from the top of cloud or haze layers combined with turbulence up to a definite limit offers a

more satisfactory explanation. Taking, for example, a cloud sheet at a temperature of 273° abs with air of 40 per cent humidity above it, and assuming the eddy conductivity within the cloud to be 10<sup>3</sup> C G S units, the cooling of the top of the cloud by radiation in 10 hours comes out to be of the order of 25° C. If the eddy conductivity is increased to 10<sup>4</sup> C G S units, the cooling becomes 8° C, with another cloud sheet above with the temperature of its base at 263° abs the cooling comes out to be 5° C and 2° C respectively. The spreading upward of this cooling by radiative diffusion and eddy conduction has been calculated in the way suggested by Brunt.<sup>4</sup> The temperature-height curves thus obtained above the cloud agree with observed results.

On the basis of Mendenhall and Mason's experiments<sup>5</sup> on the "stratified subsidence of suspended particles", a mechanism has also been suggested for the production of a number of haze layers in the atmosphere met with in one single aeroplane ascent after the passage of a cyclone. These haze layers give rise to humidity discontinuities, and in some cases to cloud sheets later, which in turn are responsible for the development of dry inversions.

### Thermal Chlorination of Methane.

ON correlating the data in two recent papers<sup>1, 2</sup> on the thermal chlorination of methane and methyl chloride, it appears that there is a possibility that the four hydrogen atoms of methane are not simultaneously equally available for chlorination, but that after the substitution of one of them the other three are

Pease and Waltz<sup>2</sup> have shown that the chlorination of methyl chloride proceeds more rapidly than the chlorination of methane, that is, the relative reaction velocities of methane and methyl chloride chlorination are not in the proportion of the numbers of hydrogen atoms in the molecules, and therefore not in agreement with this postulate in the derivation of Martin and Fuchs's<sup>3</sup> kinetic formulæ. The published results of Mason and Wheeler's experiments on the chlorination of methyl chloride (these are, of course, liable to error on account of the approximate fractionation methods used, though the error has been corrected for so far as possible) are in agreement with Martin and Fuchs's kinetic formulæ for a three-stage reaction, from which it would appear that the three remaining hydrogen atoms are equally available for chlorination, and that the relative reaction velocities for the successive stages are proportional to the numbers of residual hydrogen atoms.

Although Mason and Wheeler's results with methane are in fair agreement with the kinetic four-stage formulæ of Martin and Fuchs, it is apparent on close inspection that the amounts of methyl chloride and methylene chloride formed are respectively less and more than the amounts demanded by theory, although it would be expected from calculation that the methyl chloride would not be underestimated in the experiments with a large excess of methane. The results are in general agreement with those of Martin and

Fuchs (loc cit), who showed that the last three stages had velocities proportional to the numbers of residual hydrogen atoms

The point cannot definitely be decided until more complete experimental data are available. Further investigations are being carried out, these, it is hoped, will throw more light on the matter, or provide a different explanation.

The conclusions, however, are in harmony with those of Harkins and Bowers<sup>4</sup> on the carbon-halogen bond as related to Raman spectra, in that the frequency of the C-Br bond is constant in normal compounds with the exception of  $\text{CH}_3\text{Br}$ . The results of West and Farnsworth<sup>5</sup> on normal chlorides show that the frequency of the C-Cl bond is constant except in methyl chloride.

#### Preparation of Sulphuric Acid free from Nitric Acid

For the analysis of the nitrate content of sea water, and for certain tests on alkaloids, it is necessary to have sulphuric acid free from all but the most minute amounts of nitric acid. After testing a number of British and foreign samples of pure sulphuric acid, Harvey<sup>1</sup> reported that he had found the 'nitrogen free' sulphuric acid specially supplied by the British Drug Houses, Ltd., to be satisfactory, though the 'analytical reagent' acid was not so. Even in the purest acid the reduced strychnine reagent of Denigès demonstrated the presence of nitric acid, which was estimated by extrapolation after adding known amounts of nitrate, reckoned as milligrams of nitrate nitrogen per cubic metre of sea water.

Early this year I encountered the same trouble owing to nitric acid when applying the diphenyl benzidine method of Letts and Rea<sup>2</sup> to the estimation of nitrate in sea water. It was found, however, that all nitric acid could be removed from the sulphuric acid by the cautious addition of ammonium sulphide. It was later found preferable to use hydrogen sulphide. This reduces the nitric acid, and the amount of sulphur formed is too small to be visible or to render the acid even slightly turbid. In practice it is better not to remove all the nitric acid, but to leave a trace sufficient to give the faintest perceptible colour with the reagents. Excess of the reducing agent would, of course, render the test insensitive through the production of sulphur dioxide. The last supply of 'nitrogen free' acid received gave no perceptible colour with the reagent after standing for a day.

#### National Needs.

I AM glad to have occasioned the rejoinder of H. E. A. in NATURE of Dec 26, though I am frankly horrified at his proposal for a *coup d'État* followed by the dictatorship of the Royal Society. I fear the adventure would end with that august body in the tumbrils.

H. E. A.'s other suggestion, that there should be inaugurated a kind of educational crusade to develop the scientific attitude of mind in the ordinary citizen, is one of the most important ever made to the world of science. In spite of the immense social importance of the work and temper of science, her disciples do not make any effort to explain themselves to the public comparable with the electioneering effort of a political party or the missionary effort of a church.

Something more is needed than gentle remonstrances addressed to schools and universities, begging them to include some science in the courses followed by their non-specialist students. Schools and universities are only part of the wider problem of the insufficiency of public thought to manifest social needs. I should like to see the scientific world dealing with the public mind by every modern device of persuasion, including school, university, press, radio, cinema, and the various institutions for adult education, in an organised attempt to influence the thought of this generation. I believe that such an effort, generously conceived and carried into effect, would be astonishingly successful.

I share the doubt, expressed in the leading article in the issue of Jan 9, as to the appropriateness of the Royal Society as a pivotal body for such a task. The Society could contribute the reflected glory of its immense prestige, but so far as I know it possesses no machinery for carrying out this kind of work.

The various concrete projects which peep out from time to time from beneath the generalities of the present discussion could be carried through by a comparatively small group of people, with the assistance of allies called into co-operation for special purposes. The members of such a group would need to be people of scientific training with a flair for public work and with the proper contacts within and without the scientific world. It would not be difficult to find a score of such men and women. The really difficult problem would be to finance their work. Such expenditure would in the end repay the scientific profession very handsomely in hard cash.

LOUIS ANDERSON FENN

Birmingham, Jan 5

#### Discovery of *Eurytemora thompsoni* at Lancing.

THE discovery of *Eurytemora thompsoni* by Mr Lowndes at Lancing<sup>1</sup> adds one more puzzle to the problem of the distribution of the fresh- and brackish-water fauna. A rather similar case of unaccountable distribution is that of *Acartia tonsa*, a copepod which was discovered in 1927 in brackish water in a canal at Caen (Normandy). This is a coastal species of very wide distribution, recorded from the Pacific, Indian Ocean, and North American coast of the Atlantic, but not from its eastern shores. In the case of the anemone, *Sagartia luciae*, the agency of ship transport is fairly obvious, but it is not very convincing for Calanoid copepods, especially when, as in the case of *E. thompsoni*, the locality has no connexion with any harbour. Still, such transport cannot be excluded. I have found *S. luciae* myself in a brackish pond in Norfolk far from any port.

It may be worth mentioning here that I specially looked for, and found, *S. luciae* in Port Said harbour, though it is not mentioned in the reports of the Cambridge expedition to the Suez Canal. Presumably the specimens were lost.

## Research Items.

## Egyptian and Peruvian Mummies under the X-Rays.

—An X-ray study of the unopened Egyptian and Peruvian mummy-packs in the collections of the Field Museum of Natural History, Chicago, by Mr Roy L. Moodie, has yielded valuable material bearing on our knowledge of diseases in ancient times. An account of the investigation, accompanied by 76 plates, mostly from X-ray photographs, is published in vol 3 (Anthropology) *Memours* of the Museum. The employment of X-rays has made possible the examination of whole skeletons, but it is subject to limitations, of which the most serious is that it does not reveal all lesions, especially when they are slight or covered by more or less dense tissue. Nor does it show trepanning or injuries from clubs and the like. Percentage of disease or injury among the fifty-three mummy-packs examined is high, 10.52 per cent of the Peruvian pre-Columbian mummies and 40 per cent of the Egyptian being affected. The examination of the Peruvian children showed no evidence of rickets, but there is a trace among the Egyptians. The Egyptian mummies showed arthritis, arteriosclerosis, and absorptive osteitis resulting from pyorrhœa. Owing to the masses of pitch or sand-sprinkled tar which obstructs the head, and masks, ornaments, etc., the interpretation of the teeth is not possible. There is a doubtful case of hypertrophied liver. In the Peruvian mummies arthritis and arteriosclerosis are rare. Few cases of caries can be identified, owing to the intervention of various objects. Pyorrhœa and calculus are common. A rare example of impaction of the mandibular third molars was observed. Nasal disturbances of the turbinates was revealed, though none is sufficiently clear to admit diagnosis. Aural exostoses were a frequent cause of partial or complete deafness. Otitis media occurred, and mastoid infection was detected. Mummified animals from both Egypt and Peru were also examined.

**Habits of Californian Red Tree Mouse**—The red tree mouse, *Phenacomys longicaudus*, builds its nest as a rule amongst the branches of a Douglas fir or a great fir (*Abies grandis*), but this seems to be simply because it finds there suitable support in proximity to a rich food supply consisting of the green leaves of the fir trees. In eating these leaves, the mice show a curious habit, described by Seth B. Benson and Adrey E. Borell (*Jour. Mammalogy*, vol 12, Aug 1931). The needle, bitten off a twig, would be held in both fore paws, then a stripping process commenced, the outer side of the needle being shredded off from base to tip, as it was passed from right to left. Then the needle would be reversed and turned over, and the mouse, passing the leaf from right to left as before, would start at the apex and strip off the other edge of the needle. Thus the resin ducts, placed in the margins of the leaf, were got rid of, and the remaining edible portion, held in the left fore paw, was eaten as one would eat a stalk of celery. That the object of the stripping was to remove distasteful portions of the leaf was indicated by the habit of the mice of eating, without preliminary treatment, very young needles in which resin ducts were not fully formed. They were never seen to eat the resin duct portions and discard the medullary portion of the needle.

**Wild Sheep Hybrid**—In 1906 and later, a few Mouflon sheep, described as from Sardinia and Corsica, were introduced by Lord Revelstoke on Lambay Island, Co. Dublin, and bred there successfully, increasing for a number of years. Some were shot during the War, and by 1927 two males only were left alive. A large flock of Black Welsh Mountain

sheep were free on the island at the same time, but no interbreeding took place while there were any Mouflon ewes alive. Dr J. A. Fraser Roberts (*Jour. Genetics*, vol 25, no 1) has made a study of the later crosses, after carefully describing the Mouflon coat. In the years 1928-29, twenty-eight  $F_1$  lambs were born, 15 self-blacks, 8 black reversed badger-faces, and 5 whites.  $F_2$  and back-crosses are also described. The results show that the Mouflon is a recessive black, bearing the factor for reversed badger-face pattern. Nine other factors are shown to be absent: dominant black, dominant brown, white, badger-face, black head, white collar, the factor or factors for grey colour, and the two factors that give coloured or spotted faces and legs in a white sheep. Photographs are given of some of the hybrids and of several wild species of sheep. The paper concludes with notes on the coat colours of various wild species. The Mouflon has the darkest pattern of any except the Himalayan Bharal. The undercoat in all is brown, or white, not black, and all members of the Mouflon and Urial groups show reversed badger-face pattern. The Barbary sheep of North Africa is reddish fawn self-coloured, without this pattern.

**Deep Sea Fishes**—Mr Albert Eide Parr in two papers published in the *Bulletin of the Bingham Oceanographic Collection*, Peabody Museum of Natural History, Yale University, vol 2, Art 4, and vol 4, Art 1, October 1931, revises the classification of a number of deep sea fishes and gives useful keys for their identification ("Deep Sea Fishes from the Western Coast of North and Central America" and "A Practical Revision of the Western Atlantic Species of the Genus *Cutharichthys* (including *Etropus*)"). Among the fishes described in the first paper there are many interesting new forms. The new genus *Dolichodon* is suggested for Norman's *Dysalotus macodon* and a new species named *Dolichodon normani*. These differ from *Dysalotus*, here restricted to having only two rows of teeth in each jaw, the inner series sharply differentiated from the outer by an abrupt and very great increase in the size of its teeth and by their strong curvature. In the second paper, there are special observations on *Cutharichthys crossotus* from both the Atlantic and Pacific side of central and southern North America. The author was unsuccessful in differentiating the full grown individuals, but shows that there is a considerable difference in the relative body widths with increasing size, the Atlantic specimens only showing a very slight indication of a gradual increase in relative width with increasing size, whilst those from the Pacific show a very marked and consistent difference. A new subspecies is based on this difference, the two forms being named *Cutharichthys crossotus atlanticus* and *Cutharichthys crossotus crossotus*. There are very distinct secondary sexual characters in *Cutharichthys unicornis*. The young males less than 35 mm. are like the females outwardly, but very soon the width of the interorbital space in the male rapidly increases and also there is a great development of cephalic spines.

**Genetics of the Dahlia**—The common dahlia, *D. variabilis*, is well known to show great variability. Mr W. J. C. Lawrence has brought forward further evidence (*Jour. of Genetics*, vol 24, No 3) that it is an octoploid species (with sixty-four chromosomes) produced by the crossing of two tetraploid species, one carrying factors for ivory and magenta flowers, the other for the yellow-orange-scarlet series. Several species are found to have thirty-two chromosomes and one (*D. Merckii*) thirty-six. From a study of the

various pigments and their inheritance, it is suggested that the yellow flavone colour is determined by a factor (*Y*) which is tetrasomic and segregates at random, while the ivory factor (*I*) gives disomic ratios only. Flavone inhibitors are also present, as well as anthocyanin factors—*A*, paler and cumulative in effect when present in multiple, *B*, deeper and probably also cumulative. The genetic evidence indicates that *I* and *Y* are carried by homologous chromosomes derived from different ancestral species. Similarly, *A* and *B* are carried by two differentiated quadrivalent sets of chromosomes, which probably underwent their chemical differentiation parallel respectively to *I* and *Y*. It is further suggested that the tetraploid species have been derived from a diploid ancestral stock in which the two flower-colour series differentiated. In *D. variabilis*, secondary chromosome associations of four or more chromosomes are found in meiosis, and in crosses with *D. coronata* ( $2n=32$ ) many of the *coronata* chromosomes pair with *variabilis* homologues, indicating that *coronata* is perhaps one of the ancestors of *variabilis*.

#### Tuber Indexing for controlling Potato Virus Diseases

—The production of stocks of potatoes free from virus diseases is an urgent problem. Large sums of money are lost annually by the potato-growing community through the depredations of crinkle, mosaic, and leaf-roll. It seems that any method of ensuring freedom from these maladies would turn potato-growing from being somewhat of an incubus to an economic success. Americans for many years have practised the cutting-out of a small part of a tuber containing an eye, which is grown in a warm greenhouse in winter. The state of health of the plant thereby produced shows whether the original tuber (which is afterwards planted in the field) was infected with any virus disease. A report by J. E. Kotila (*Michigan State College Tech. Bull.*, No 117, 26 pp., 1931) has recently been published. This shows that the method of tuber indexing works well on a large scale in Michigan, so far as the production of disease-free clones is concerned. Such testing must be followed by adequate isolation of the improved stocks from diseased crops. The report is rather disappointing, however, in that there are too few comparative yields of unimproved stocks. The high summer temperatures of the middle-west States mask the symptoms of virus diseases and cause less reduction in yield than would occur in cooler climates. Masking takes place in Great Britain only when summers are hot, there was little masking last year. If tuber indexing gives good results in America, would it not give better results in Great Britain, where reductions in yield by the diseases are more serious than in the United States?

**Water in Granitic Magmas**—The results of an important investigation by R. W. Goranson on the solubility of water in granite-glass (*a*) as a function of pressure from 500 bars to 4000 bars at 900° C. and (*b*) as a function of temperature from 600° to 1200° C. at 980 bars, are presented in the *Amer. Jour. Sci.* for December 1931. The granite-glass was obtained by melting the normal biotite-bearing muscovite-granite of Stone Mountain. The solubility of water in this glass at 900° C. increases from 3.75 per cent at 500 bars to 9.35 per cent at 4000 bars. The solubility at 980 bars decreases by 0.3 per cent per 100° C. rise in temperature over the range 600°–1200° C. Essentially the same results were found in the case of a natural rock-glass (obsidian) from Mount Kiamis, Japan. It is concluded that natural glasses with 8–10 per cent of  $H_2O$  + should be extremely rare, and this is shown to be borne out by published analyses of fresh obsidians. Reasons are presented for consider-

ing that granitic magmas may have had a relatively high water content, and that such water would have an important effect in lowering the crystallisation temperatures. At 10 km depth and 1000° C., the amount of water held in solution could be as much as 6 per cent. If the magma could ascend between impervious walls, the solubility would fall and the excess water would accumulate until the overlying rocks became incompetent to withstand the pressure. Rupture would then take place with explosive force, and lead to the development of volcanic phenomena.

**Earthquakes of the Channel Islands**—Though among the strongest that are felt in the British Isles, the earthquakes of the Channel Islands have not received the attention that they deserve. In a memoir recently published by the Société Jersiaise, Mr. A. E. Mourant has thus well supplied a long-felt want. The list of all the known earthquakes since the year 824, contains four (in 1799, 1878, 1889, and 1926) that must have disturbed areas of more than 115,000 sq. miles, an area greater than that of any earthquake of strictly British origin. The earthquakes since 1926 have been investigated by the author, and of these more detailed accounts are given, especially of those of July 30, 1926, and Feb. 17, 1927. The stronger shocks have certain characteristics in common. Most of them originated in a focus in lat. 49° 11' N., long. 1° 42' W., or about nine miles east of St. Helier, thus nearer to France than to Jersey. They tend to recur at regular intervals of 12 yr. ± 7 mon., while an examination of all the Jersey earthquakes, great and small, shows some evidence for periods of four years and one year.

**Thermal Conduction in an Electric Field**—The *Zeitschrift für Physik* for Oct. 30 contains an account of experiments performed by W. Bonwitt and G. Groetzinger at Vienna, which show that heat losses in a gas are changed to a slight extent by an electric field. The method used was that in which a wire supported in the gas is heated electrically, and the equilibrium temperature which it assumes under the influence of the electric current and thermal loss through the gas is measured from its resistance. Air and carbon dioxide give only a very small effect, but it is much larger and can be readily followed with certain organic vapours. With acetone vapour at a pressure of 175 mm. of mercury, for example, a decrease of one-tenth of a degree in the temperature of the wire was recorded in a field of 1000 volts per cm. The magnitude of the effect depends upon the dielectric constant of the gas, increasing rapidly with the permanent electric moment of the molecule, and its sign always corresponds to an increase of thermal conductivity in the field.

**Photographic Photometry**—In view of the many applications of the measurement of the blackening of photographic plates for photometric purposes, it is disturbing to find in a paper by P. C. Keenan in the September issue of the *Astrophysical Journal* that large errors may arise if the time between exposure and development is not standardised. It appears that the effect is somewhat erratic, depending upon a variety of conditions, but what is generally observed is that the latent image increases in intensity for a few hours after exposure and then tends to fade off again. In the tests which are described, increases of density of the order of ten per cent were found to occur after two hours, the increase being greatest for moderately strong blackening. It is concluded that although the effect is normally likely to be quite small, yet in exceptional cases it may be important, so that in photometry which aims at any considerable degree of precision, images of which the densities are to be

compared directly should be developed at as nearly the same time after exposure as possible

**A Possible Hydrogen Isotope of Mass 2**—There is some evidence from atomic weight determinations that hydrogen should have isotopes of masses 2 and 3. If they exist, it can be shown from thermodynamical reasoning that molecules of the types  $\text{H}^1\text{H}^2$  and  $\text{H}^1\text{H}^3$  should concentrate relative to the common  $\text{H}^1\text{H}^1$  molecules in residues from the evaporation of hydrogen near the triple point, whilst it is known from simple spectroscopic theory that the heavier atoms would have a displaced Balmer spectrum. Work undertaken on these considerations is reported by H. C. Urey, F. G. Brickwedde, and G. M. Murphy in the last issue of the *Bulletin of the American Physical Society* for 1931. The atom  $\text{H}^3$  has not been detected, but it has been found that the lines  $\text{H}\beta$ ,  $\text{H}\gamma$ , and  $\text{H}\delta$  are accompanied by weaker lines which agree within the experimental error of 0.01 Å with the positions calculated for an isotope of mass 2. The reputed isotope lines have the same width as the main lines and are definitely more intense with the treated material, although they are present when ordinary hydrogen is used.

**Chromium Plating**—The chromium plating now so much used to prevent tarnishing of metal fittings of all kinds has been found to be slightly porous and not to afford sufficient protection against corrosion of the base metal, such as steel, on which it is deposited. It has been necessary to deposit copper or nickel on the base metal before the chromium is applied, and the Bureau of Standards, in co-operation with the American Electroplaters' Society and the American Society for Testing Materials, has been investigating the possibility of producing less porous deposits and so reducing the thickness of the copper or nickel protection necessary. The results are summarised in a paper by Messrs W. Blum, W. P. Barrows, and A. Brenner in the October issue of the *Journal of Research* of the Bureau. Both the porosity and the cracking of the chromium deposit increase rapidly in the first twenty-four hours and more slowly for several weeks at room temperatures. Heating for a short time to 200° C increases the ultimate cracking. A slight increase in the chromic acid and of the ratio  $\text{CrO}_3$  to  $\text{SO}_4$  in the depositing tank, an increase of

temperature of the tank to 55° or 65° C and a decrease of current density, all decrease the porosity of the deposit.

**Purification of Radon**—G. H. Henderson, in the *Canadian Journal of Research*, p. 466, describes a simple apparatus for the purification of radon for radium therapy, which differs in some respects from the ordinary practice. Potassium hydroxide is used to remove carbon dioxide and most of the water, and since phosphorus pentoxide is dispensed with, only one Toepler pump and fewer valves and stopcocks are necessary. The impurities are removed by sparking and the excess of hydrogen is allowed to escape through an electrically heated palladium tube. The apparatus, which was designed by W. G. Moran, has been in use in the Victoria General Hospital, Halifax, for three years with very satisfactory results. The radon is readily concentrated to 100 millicuries per cubic millimetre, the actual purification taking from two to five minutes. The amount of radium in solution in the apparatus is 200 mgm, but there seems no reason why it should not work equally well with larger quantities.

**Vitamin B and Phytase**—Since Teru-Uchi has shown that experimental beri-beri of pigeons (avitaminosis B) is caused by the action of a toxic substance, orizotoxin, extractable from polished rice, and Iwata has found that lysocitin, a substance formed from lecithin by the action of certain enzymes, occurs in polished rice, the possibility of a relationship between lysocitin and orizotoxin arises. A series of experiments made by Cuboni and described in the *Rendiconti of the Reale Istituto Lombardo di Scienze e Lettere* (vol. 64, parts 11-15, 1931) shows that all the symptoms of beri-beri may be reproduced in chickens by injections of orizotoxin, whereas injection of lysocitin has no such effect. Various analogies in behaviour between phytase—which, as Belfanti and Contardi showed, prevents and cures beri-beri—and vitamin B are pointed out, and the conclusion is drawn that these two substances are certainly closely related and probably identical. Further similarity between phytase and vitamin B is revealed by experiments—described in the same issue—carried out by Arnaudi, who finds that the growth of yeast and certain other micro-organisms is accelerated in the same way by the two substances.

### Astronomical Topics.

**The Orbit of 61 Cygni**—This well-known double star has always attracted much attention from the wide distance between the components and the large proper motion, it was for the latter reason that Bessel selected it for parallax tests with the Königsberg heliometer, obtaining the first reliable stellar distance. Though it is such a near neighbour, the period is so long that its determination has baffled many investigators. In fact, at the end of the last century some American astronomers denied that it was a binary at all. However, M. T. Lewis, in his memoir on the Struve double stars, gave a diagram on a large scale of the observations up to 1900, which exhibited the curvature of the path in a palpable manner. At an even earlier date Dr. Peters had published an orbit in *Astr. Nach.*, with a period of nearly eight hundred years.

Mr. Fletcher read a paper on this star at the January meeting of the Royal Astronomical Society. He considers the binary character absolutely established, and anticipates that the period would be found to lie between 700 years and 1000 years, agreeing with the estimate of Peters. In the discussion, Dr. Jackson pointed out that the uncertainty in the period

does not introduce much error into the determination of the masses, as this depends in the main on the curvature of the arc over which the observations extend. Mr. Fletcher also considered the observations of radial velocity of the components, but as the difference between them is small, they do not add much to the accuracy of the orbit-determination.

**Possible Early Observation of the Bielid Meteors**—*Pop. Astr.* for December contains a translation by Willard J. Fisher of an article by W. Klinkerfues that appeared in *Göttinger Nachrichten*, April 3, 1873. It is evidently very little known among astronomers. It establishes with great probability, on the basis of a record by Theophanes, that Biela's comet and the accompanying meteors were both observed at Byzantium in the year A.D. 524. It is noted that the record mentions both comet and meteors together, so that a connexion between them was suspected even then. Klinkerfues also concluded that the comet observed in China in November A.D. 1162 was Biela's. In both the years mentioned the comet, if correctly identified, would have been near the earth, so that its visibility with the naked eye is not improbable.

## Prize Awards of the Paris Academy of Sciences.

AT the annual meeting of the Paris Academy of Sciences, the prizes and grants awarded for the year 1931 were announced as follows

*Mathematics*—The Francœur prize to Jacques Herbrand, for his work on the theory of bodies of numbers

*Mechanics*—The Montyon prize to Hippolyte Parodi, for his work on the electrification of railways and on ballistics, the Poncelet prize to Henri Chipart, for his work in mathematical physics and mechanics

*Astronomy*—The Lalande prize to Irénée Lagarde, for work relating to astronomical calculations, the Valz prize to Henri Chrétien, for his work in astronomical optics, the G de Pontécoulant prize to Jean Chazy, for his work in analytical and celestial mechanics

*Geography*—The Gay prize to Henri Roussilhe, for his work on the use of aerial photography in topographical surveys on the large scale, the Tchihatchef prize to Charles Crevost and Alfred Pételot, the two authors of vol 5 of the catalogue of the products of Indo-China (medicinal products), the Alexandre Givry prize to André Gougenheim, for his work in hydrography

*Navigation*—The Prix de la Marine between Eugène Burlot (3000 francs), for his theoretical and experimental studies on explosives, Charles Bertin (1500 francs), for his method of marine and aerial navigation, and Gabriel Voitoux (1500 francs), for his book on trans-Atlantic aerial navigation, the Plumey prize to Marcel Edmond Gautier, for his memoirs dealing with combustibles used in Diesel motors

*Physics*—The Kastner-Boursault prize to Francis Perrin, for his work on fluorescence, the Gaston Planté prize to Émile Pierret, for his researches on high frequency electromagnetic waves, the Hébert prize to Gustave Ribaud, for his treatise on pyrometry, the Henri de Parville prize to Georges Darrieus, for the whole of his work in electrotechnics, especially the calculations on high tension lines, the Hughes prize to René de Mallemann, for his work on magnetic rotatory polarisation, the Pierson-Perrin prize to Georges Reboul, for the whole of his researches on the properties of semi-conducting substances, the Clément Félix foundation to Mlle Madeleine Chenot, for the continuation of her researches on the high frequency discharge in rarefied gases

*Chemistry*—The Montyon prize (unhealthy trades) to Léon Brunel, for his contributions to various important problems of public hygiene, and an honourable mention (1500 francs) to Georges Champetier, for his work on the protection of civil populations against mustard gas, the Jecker prize to Ernest Fournéau, for the whole of his work in organic chemistry, the Cahours foundation between Arthur Brunel, for his work on plant ferments, and Jean Dœuvre, for his studies on citronellol and rhodinol, the Houzeau prize to Henri Marcelet, for his work as a whole

*Mineralogy and Geology*—The Delesse prize to Léon Carez, for his geological work on the Pyrenees, the Victor Raulin prize to Eugène Raguin, for his geological work in the Alps and the Central Massif, the Joseph Labbé prize to Lucien Thiébaud, for his work on the clay-limestone sediments of the Paris basin

*Botany*—The Desmazières prize to Gaston Ollivier, for his work "Étude de la flore marine de la Côte d'Azur", the Montagne prize to Pierre Frémy, for his memoir on the Myxophyceæ of French Equatorial Africa, the Jean Thore prize to Georges Deflandre, for his monographs on *Trachelomonas* and *Arcella*, the Fons Méhœcq prize to Jean des Cilleuls, for his work

on the plankton of the Loire the de Comcy prize to Adolphe Prunet, for his work on the diseases of the chestnut tree, the Jean Rufz de Lavison prize to Émile Michel-Durand, for his memoirs on the variation of the carbohydrate substances in leaves and on the tannic compounds

*Anatomy and Zoology*—The Cuvier prize to François X Lesbre for the whole of his work on comparative anatomy, morphology, and teratology of mammals, the Savigny foundation to Robert Dollfus, for his work in the Red Sea and Suez Canal

*Medicine and Surgery*—The Montyon prizes A Montyon gold medal to Edoardo Peironcito, for the whole of his scientific work Prizes of 2500 francs to Maurice Auvray, for his memoir on diseases of the skull and brain, to Henri Chabanier and Carlos Lobo-Onell, for their memoir on functional exploration of the kidneys, to Maurice Villaret, François Saint-Girons, and Louis Justin-Besançon for their memoir on the physiological, clinical, and therapeutic study of peripheral venous pressure

Honourable mentions (1500 francs) to Émile Césari, for his researches on the antigenic function of the lipoids, Paul Géraud, for his researches on the exchanges of ions between yeast cells and saline solutions, Mme Mélna Lipinska, for her memoir on women and the progress of medical science

The Barbier prize to Casimir Peirier, for his contribution to the study of the oil-bearing plants of the Cameroons, the Breant prize between (2500 francs each) Maurice Langeron, for his studies on the pathogenic fungi, and Pierre J Teissier and Florent Coste, for their book on the physio-pathology of scarlet fever, the Godard prize between (500 francs each) Louis Berger, for his memoir on the internal secretion cells in the sexual glands in man and woman, and Fritz Busser, for his book on epithelial tumours of the kidney in the adult the Chaussier prize to Victor Morax, for the whole of his medical work, the Mège prize to Jean Gautrelet, for his work on the influence of adrenalin on the variations of the alkaline reserve, the Bellion prize to Raoul Lecocq, for his book on food and life, the Larry prize to Maurice Pilod, for his studies on tuberculosis, Louis Izard and Jean des Cilleuls receiving an honourable mention for their book on military hygiene, the Argut prize to Pierre Ernest Roucaÿrol, for his memoir on direct 'd'arsonvalisation' in the treatment of blennorrhagia

*Physiology*—The Montyon prize to Charles Dhéré, for his studies on biological fluorescence, the Pourat prize (in equal parts) between Maurice Fontaine, for his experimental researches on the reaction of living beings to high pressures, and Fernand Obaton, for his memoir on the evolution of mannitol in plants, the Philpeaux prize to Robert Bonnet, for his work on metabolism

*Statistics*—Montyon prizes (1000 francs) to Pierre Caloni, for his memoir on the statistics of accidents and organisation for their prevention, and to Jean Fischer, for his statistical studies of the rivers Adour, Garonne, and Gironde

*History and Philosophy of Science*—The Binoux prize to Louis de Nussac, for his book on "Pierre Andre Latreille"

*Works of Science*—The Henri de Parville prize between Émile Guyénot (2500 francs), for his books on variation, evolution, and heredity, and Paul Dorveaux, for his researches on the members and correspondents of the Royal Academy of Sciences, 1666-1793

*Medals*—The Berthelot medal was awarded to Henri Marcelet

*General Prizes*—The Grand prize (physical sciences) to Paul Fallot, for his geological work in the Balearic Islands, Andalusia, and Morocco, the Bordin prize to René Garnier, for his work on the problem of Plateau, the Lallemand prize to Albert Chauchard and Mme Berthe Chauchard, for their physiological researches on the sympathetic and parasympathetic nervous system and on the brain, the Maujean prize to Gustave Bouffard, for his work on tropical diseases, the Petit d'Ormay Prize (mathematical sciences) to Gaston Julia, for the whole of his mathematical work, the Petit d'Ormay prize (natural sciences) to Pierre Lesne, for his entomological work, the Jean Reynaud prize to the late Paul Appell, for the whole of his scientific work, the Baron de Joest prize to Gustave Hinard, for his work on sanitation and oyster culture, the Parkin prize to Marius Dalloni, for his work in connexion with the expedition to Tibesti, the Santour prize to Henri Devaux, for his work on the properties of thin layers deposited on the surface of liquids, the Lonchampt prize to Eugène Derrien, for his work in biochemistry, the Henry Wilde prize to Edmond Rothé, for his geophysical work, the Gustave Roux prize to Henri Bésairie, for his work on the geology of Madagascar, the Thorlet prize to Adolphe Richard.

*Special Foundations*—The Lannelongue foundation to Mmes Cusco and Ruck, the Hélène Helbronner-Fould prize to Mme Marc Bel, in recognition of the exploratory work done by her late husband.

*Prizes of the Grands Écoles*—The Laplace prize to Jean Latourte, the L. E. Rivot prize between Jean Latourte, Albert Gabriel Bureau, Jean Gaston Chauchoy, and Alphonse Desiré Charles Louis Cachera.

*Foundations for Scientific Research*—The Trément foundation to Maurice Lebrun, for his work on electric welding, the Gegner foundation to Eugène Estanave, for his work on photography, the Hirn foundation to Yves Milon, for geological and palæontological work in Brittany, the Henri Becquerel foundation to Edgar Pierre Tawil, for his work in piezo-electricity.

#### THE LOUTREUIL FOUNDATION

The Academy has made the following grants from this fund

1 *Researches on Definite Problems*—Julien Costantin (3000 francs), for researches on applied botany in the Alps, Gabriel Marotel (2000 francs), for experimental researches on the disease of the fluke worm and its treatment, A. Aron (2000 francs), for prosecuting researches on the properties of thin metallic plates, James Basset (500 francs), for laboratory researches on the influence of high pressures on physical and chemical phenomena, Claude Gautier (1000 francs), for

work on the physiological synthesis of the proteins, Charles Marie (3000 francs), for researches on the ammonia-oxygen gas battery, Raymond Ricard<sup>4</sup> (2000 francs), for spark spectra of metals by means of electrodeless discharges, Gaston Delépine (10,000 francs), for the continuation of work commenced by him and by his pupils, especially on the Carboniferous of Asturia, Abel Gruvel (2000 francs), as a contribution to his scientific and applied researches on the fauna of the hydrographic network of Syria.

2 *Purchase of Maternal*—Emilio Damour (2000 francs), for the purchase of an apparatus controlling combustion by thermal conductivity, René Dubrisay (5000 francs), for the purchase of a microscope, Augustin Mesnager (2000 francs), to contribute to the purchase of an apparatus for measuring the distribution of the stresses in various elastic solids, Casimir Monteil (5000 francs), for the purchase of a Jacquet tachygraph.

3 *Libraries*—École polytechnique (10,000 francs), for the library, École nationale vétérinaire d'Alfort (10,000 francs), for its library, École nationale vétérinaire de Lyon (13,000 francs), for assisting the replacement of the library destroyed by fire, École nationale vétérinaire de Toulouse, for its library.

4 *Publications*—"Faune des Colonies françaises" (5000 francs), for its publications, Albert Peyrot (6000 francs), for the completion of the "Conchologie néogénique de l'Aquitaine", Section of Terrestrial Magnetism and Atmospheric Electricity of the National Committee of Geodesy and Geophysics (6000 francs), for the publication of charts of magnetic anomalies in France, Georges Perrier (10,000 francs), for the calculations contained in the publication dealing with latitudes by meridional observations of the Mission de l'Équateur, Ministry for the Colonies, Service central de la Météorologie coloniale (15,000 francs), for starting a publication on the scientific observations made in the French overseas dominions, Office international de Documentation et de Corrélation pour la Protection de la Nature (2000 francs), for the publication of leaflets concerning the French colonies, Mme Victor Noury foundation, between Paul Vignon (3000 francs), for his introduction to experimental biology, Raymond Decary (2500 francs), for his work entitled "L'Androy", the late Gabriel Grimaud (2500 francs), for his book on the Rohan-Chabot expedition, and Jehan Albert Vellard (2500 francs), for his studies of the poisonous spiders of southern Brazil, the Charles Bouchard foundation to Serge Metalnikov, for his memoir on the rôle of the conditional reflexes and of the nervous system in immunity, the Roy Vaucouloux foundation to Antoine Lacassagne, for his work on the action of radiations on healthy and cancerous tissues.

#### Measuring Atmospheric Pollution.

AT the present time, the investigation of atmospheric pollution—conducted in Great Britain by the Department of Scientific and Industrial Research through the agency of a Research Committee—is mainly carried out with the aid of three instruments, all designed by Dr J. S. Owens, Superintendent of Observations to the Committee. The first, known as the deposit gauge, is designed for the purpose of measuring the total amount of impurity deposited on a given area. It consists essentially of a rain-gauge, in which the ordinary copper collecting funnel is replaced by a large glass receiver. The rain, with the impurity, is collected for a definite period, usually a calendar month, and then analysed. The second and third instruments are respectively the automatic air filter and the jet dust counter. The former gives a semi-con-

tinuous record of the concentration of suspended impurity in the atmosphere. The latter provides a means of determining the number of solid particles in a given volume of air and of ascertaining the physical nature of the individual particles. Dr Owens has recently made important improvements to both these instruments, and, although no new principles are involved, their range of usefulness has been very greatly extended.

In the automatic air filter a known volume of air (actually two litres in standard instruments) is drawn at intervals into the apparatus through a nozzle,  $\frac{1}{8}$  in. in diameter, over which is pressed a piece of white blotting paper. In passing through the blotting paper the suspended impurity is filtered out and a darkened spot, varying in shade according to the concentration

of the impurity, is left on the blotting paper. From the results of a long series of preliminary experiments with large volumes of air, it has been possible to construct a scale of shades each representing a definite number of milligrams of impurity per cubic centimetre. The reading of the record thus consists in matching the spot against a corresponding shade in a numbered scale, an operation which can be done quite readily with sufficient accuracy. The spots are obtained in succession round the edges of the blotting paper, which is in the form of a circular disc, rotated once in twenty-four hours and controlled by clock-work.

In the earlier form of the instrument the mechanism for drawing in the air was operated by water entering a vessel provided with a syphon, which caused the water to rise and fall between two fixed levels. During the fall, air was drawn through the filter disc, an arrangement being provided for making an airtight joint between the filter nozzle and the air inlet pipe during this operation. During the rise, the filter disc was unclamped and rotated to a point fixed by the clock, the filtered air being meanwhile expelled by the rise of water in the main vessel. This form of apparatus had certain disadvantages, of which the present writer can speak feelingly as a former Superintendent of the Instruments Division of the Meteorological Office, where one of these instruments is working. The necessity for a continuous water supply is a serious drawback, and experience has made it obvious that improvements were necessary in other features of the instrument.

In the new design, the filtering mechanism is operated entirely by a falling weight which is wound to the top of its travel once a day. No outside source of power is required, and the installation of the instrument is thus not restricted to sites where these are available. The descending weight operates a crank through a train of gearing, and this crank is connected to a reinforced rubber bellows, so that at each revolution the bellows is expanded and contracted. On the down stroke one litre of air is drawn in very slowly through the filter disc, which is gripped meanwhile between the top of the filter nozzle and a corresponding 'nose' above the paper. On the up stroke air is

expelled from the bellows, the filter nozzle being meanwhile lowered out of contact with the paper. By means of an ingenious auxiliary clamping device operated by cams, the paper can be held in the same position while air is drawn in on one, two, four, or eight successive revolutions of the crank. In this way the volume of air contributing to each spot may be varied from one to eight litres, to suit the locality and season. This feature is, in my opinion, one of the chief advantages of the new instrument.

In the jet dust counter a sample of the air to be examined is caused, by means of a pump, to pass through a narrow slit behind which is a clean microscope cover glass. Before entering the slit the air passes through a cylindrical 'damping chamber' lined with wet blotting paper, and the velocity in the jet is such that a fall of pressure takes place and condensation occurs as a result of the adiabatic cooling. The water droplets and dust particles strike the cover glass, the dust adheres, and the water evaporates. In this way the dust in a known volume of air is obtained in the form of a narrow ribbon-like deposit on the cover glass, which can be examined quantitatively and qualitatively under a microscope. In the older apparatus only one record could be obtained on each glass, and, as several operations are involved, it was distinctly troublesome to get a series of records, for example, in different rooms of a building. In the new instrument, which has been put on the market by Messrs C. F. Casella and Co., Ltd., the cover glass is carried on a rotatable head which can be operated from the back of the instrument. A two-way tap also is provided, by means of which the jet can be put out of action while the damping chamber is being flushed with the new sample of air. By the aid of these devices a series of, say, eight or ten separate records can be obtained on a single cover glass, the lines of deposit intersecting at the centre like the spokes of a wheel. With a suitable eyepiece and objective in the microscope, a rough preliminary comparison of the records can be made by inspection, since portions of two or more records can be brought into the field of view simultaneously. In this way the scope of the instrument has been greatly extended and the ease of manipulation much improved. E. G. BILHAM.

### Importation of Scientific Specimens and Apparatus into Great Britain.

AS the result of a report by the Association of British Zoologists, the Council of the British Association in February 1931 appointed a committee to consider action with the view of the amelioration of the customs regulations affecting the importation of scientific specimens and apparatus. Following upon discussion between officers of the Association and the Customs House authorities, the latter have most kindly supplied the Association with a memorandum on the reliefs from customs duties on scientific instruments and cinematograph films, and from the import prohibitions on plumage likely to be of use to scientific workers, together with a note on procedure in respect of the importation of scientific specimens preserved in spirit.

The memorandum on scientific instruments and cinematograph films was supplied confidentially to enable the Association to advise *bona fide* scientific workers, but not for general publication, since some of the relaxations are extra-statutory and liable to modification or withdrawal as the interests of the revenue may demand. The British Association is, however, prepared to advise on specific applications from scientific workers or societies. Inquiries should be addressed to the Secretary of the British Association at Burlington House, London, W. 1.

It clearly emerged in the course of discussion that some of the difficulties which have been encountered by scientific workers under the customs regulations might have been avoided by previous communication with the Board of Customs and Excise, Custom House Lower Thames Street, London, E. C. 3.

The procedure with regard to the importation of scientific specimens in spirit which will apply in future is as follows.

It will be necessary that the person by whom the specimens are imported into Great Britain (or the person or institution to whom they are addressed, in the case of specimens dispatched by a consignor abroad) should be formally authorised to receive spirits free of duty for use in an art or manufacture, under the provisions of the Finance Act, 1902, Section 8. Where, however, the importer or consignee does not already hold such an authority, the collector of customs and excise at the port of importation will grant it, subject to the conditions in the next paragraph.

If the specimens are imported as ship's cargo, the necessary customs entry must describe them as specimens preserved in spirits, with a sufficient description of their nature and the approximate quantity of spirits, and must show the name and address of the importer or consignee. With the entry must be produced

letters or other documents sufficiently establishing the status of the importer or consignee and the purposes for which the specimens are imported. The collector of customs and excise will be at liberty to request further information, if he considers it necessary. Where specimens are imported in personal baggage, similar information will be asked for.

If these requirements are satisfactorily complied with, the necessary authority will be granted forthwith and the specimens admitted immediately free of any charge of spirit duty.

It is not necessary that scientific workers proceeding on expeditions abroad should take any action before leaving Great Britain. It is, however, advisable, with the view of avoiding delay, that scientific workers returning with specimens should have the letters or other documents required to establish the facts readily available, and, in the case of specimens which are being received from senders abroad, that the forwarding agent who is entrusted with the work of clearing the goods should be supplied with the necessary information and letters, etc., in good time.

### University and Educational Intelligence.

LONDON.—The following honorary appointments to the staff of the London School of Hygiene and Tropical Medicine are announced.—Dr James Fenton, medical officer of health for the Borough of Kensington, to be an additional lecturer on public health administration and practice, Mr L. W. G. Malcolm, conservator of the Wellcome Historical Medical Museum, to be a lecturer on racial hygiene.

A COURSE of nine lectures on television will be given by Mr J. J. Denton, honorary secretary of the Television Society, at the Borough Polytechnic, Borough Road, London, S.E. 1, on Thursdays at eight o'clock, commencing on Jan. 21. Further information can be obtained from the Principal of the Polytechnic.

THE finance of public elementary education as exemplified, on one hand, in certain Tyneside areas and, on the other, in a number of wealthy watering-places, forms the subject of a pamphlet entitled "The Finance of Public Elementary Education", by Mr Ernest Dyer, issued in November by the Tyneside Council of Social Service (17 Ellison Place, Newcastle-upon-Tyne). The gist of the problem discussed is indicated in the following comparison between Hebburn and Bexhill urban districts. In 1929-30 Hebburn (a Tyneside town) had 4683 elementary school children and a *ld.* rate yielded £395 or 1s. 8½*d.* a child, so that an education rate of 3s. 2*d.* in the £ was needed to finance an expenditure of £8 19s. 9*d.* per child. Bexhill, with an equal population, had only 1339 elementary school children, a *ld.* rate yielded 16s. 8½*d.* per child, and a rate of 7½*d.* in the £ (one-fifth of the Hebburn rate) enabled it to spend £13 3s. per child (fifty per cent more than Hebburn expenditure). The following year, under the operation of the Derating Act, Hebburn's rate had to be raised from 3s. 2*d.* to 4s. 7*d.*, while Bexhill's position remained unchanged. The conclusion drawn is that the formula under which grants-in-aid are fixed is becoming increasingly ineffective as a means of rectifying such disparities between rich and poor authorities, and there can be no satisfactory advance in education in the poorer districts, such as those of the Tyneside, until the State can be persuaded to accept a greater share of financial responsibility. The conclusion is to some extent invalidated by a number of important recent modifications of the grants-in-aid rules. A summary of these is given at the end of the paper.

No 3246, Vol. 129]

### Calendar of Geographical Exploration.

#### Jan 17, 1773.—Crossing the Antarctic Circle

In the sixteenth and seventeenth centuries there was a widespread belief in the existence of a great southern world. The revival of interest in geography in the eighteenth century led the Royal Society to urge on the British Admiralty the importance of research in southern waters. In 1768, James Cook sailed under orders of the Admiralty to prosecute astronomical and geographical researches in the Southern Pacific. In July 1772, under similar orders, he set out to examine and determine once and for all the question of the supposed great southern continent. His vessel, the *Resolution*, accompanied by the *Adventure*, commanded by T. Furneaux, crossed the antarctic circle on Jan. 17 of the following year. This voyage, during which he thrice penetrated the antarctic, effectively disposed of the long-cherished illusion. For it became evident that if such a continent existed it was frozen and uninhabitable. In addition, his explorations outlined the main features of the southern portions of the globe much as they remain to-day. Of further scientific interest is the fact that this voyage marked the conquest of scurvy. Cook lost but one man out of 118 on a voyage lasting 1000 days. For this service to hygiene, the Royal Society awarded him the Copley Medal in 1776.

#### Jan 17, 1839.—Balleny Islands

John Balleny, in the schooner *Eliza Scott*, left Campbell Island, south of New Zealand, to search for new land. He reached the antarctic circle in 178° E. on Jan. 29, but later, meeting heavy ice, turned westwards and discovered the group of rocky islands which bears his name. The islands were mapped and geological specimens collected. Balleny was sent out by the firm of Enderby Brothers, a London ship-owning firm trading in seal oil. This firm showed a keen interest in geographical discovery, and one of the brothers was an original fellow of the Royal Geographical Society. They had previously, in 1830, dispatched John Biscoe on a two years' voyage combining sealing and exploration. Biscoe sailed through nearly fifty degrees of longitude south of the antarctic circle and discovered the coast of Enderby Land. He did not know of Bellingshausen's discoveries, but entered that sea and discovered Biscoe Islands and the coast of Graham Land.

#### Jan 18, 1912.—The South Pole

Capt. R. F. Scott found the tent with the record that Roald Amundsen and four other Norwegians had reached the south pole on Dec. 16, 1911. Scott had reached the pole on the night of Jan. 17, but had realised from the tracks that his party had been forestalled. Scott and his companions, Wilson, Evans, Oates, and Bowers, set out on their tragic return journey. Evans fell ill and died, and the time involved in caring for their sick companion considerably delayed the party. A strong surface wind wiped out the track they were trying to follow, weather conditions were persistently adverse, the oil in the tins at the depots was insufficient, weather conditions having resulted in the perishing of the leather washers with consequent evaporation. Yet in spite of weariness and hunger, the party continued to the last to carry the geological specimens collected on the Beardmore glacier. The fossils in the specimens threw much light on the age and past history of this part of the antarctic continent, the gain to science was, however, obtained at the cost of heavy

sacrifice Oates fell ill, and Scott noted in his diary that in spite of the extra burden which this involved, Wilson and Bower remained "determinedly cheerful" Oates not only made no complaint, but also, when he realised that the burden of helping him meant death to his comrades, walked deliberately into the blizzard The weather continued adverse, and finally a prolonged blizzard held them prisoners when but eleven miles from their next depot Their bodies were found, with Scott's diary and the geological specimens, by a party led by Atkinson in the following season Scott's previous journey to the antarctic in 1902-4 had resulted in new topographical data about the southern continent and its fringing islands and new information about Ross Sea Moreover, the sledge journeys carried out by Scott, Shackleton, and Wilson had for the first time thrown light on the interior of the antarctic land The name of Scott is thus associated not only with the first attainment of the south pole by a British party, and with much sacrifice and heroism in the face of disappointment and disaster, but also with valuable contributions to scientific knowledge His successful rival, Amundsen, later met his death in going to the rescue of a fellow-explorer in the arctic

#### Jan 22, 1821 —The Russians in the Antarctic.

Admiral Bellingshausen sighted Peter I Island, the first land discovered within the antarctic circle The Emperor Alexander I of Russia had decided to embark on a scheme of polar exploration in 1819, and later sent out two expeditions, one to the arctic and one to the antarctic regions Bellingshausen was in charge of the latter and sailed from Kronstadt in July 1819 In January 1820 he discovered three small islands north of the Sandwich group, and later penetrated into the antarctic, following the edge of the icepack for nearly forty-five degrees in latitudes from 63° to 60° S His two vessels later put into Sydney harbour for repairs, and spent some time exploring the South Pacific, discovering seventeen new islands On Dec 7, 1820, they crossed 60° S, and remained south of it for two months and three days, during which time Peter I Island and Alexander Island were discovered Bellingshausen's voyage gained greatly in importance because the Russian explorer made every effort to supplement rather than to repeat Cook's voyage He thus demonstrated the existence of a continuous open sea south of lat 60° S

#### Jan 23, 1895 —First Landing on the Antarctic Continent

Capt Kristensen and C E Borchgrevink made the first landing on the southern continent The voyage was made in a whaling vessel rechristened the *Antarctic* and fitted out by the enterprise of Commander Foyen, a Norwegian whaling merchant, then eighty-four years of age The *Antarctic* started on her voyage in September 1893, and spent some time sealing at Kerguelen In September 1894 the vessel left Melbourne, and on Jan 16, 1895, sighted Cape Adare for the first time since Ross's voyage in 1839-43 On Jan 18, 1895, Borchgrevink discovered a lichen growing on the rocks of Possession Island, the first evidence of plant life obtained within the antarctic circle The same lichen was found when the party landed on Cape Adare on Jan 23. The voyage confirmed Ross's discovery of an open sea south of the pack ice as a permanent phenomenon at this season

## Societies and Academies.

### DUBLIN

Royal Dublin Society, Nov 24 —E J Sheehy The effect of an insufficient supply of vitamin D on the growth of the skeletons and internal organs of chickens Chickens which had been exposed to sunlight for ten days after hatching were thereafter kept indoors for thirteen weeks Half received a diet totally deficient in vitamin D, the other half receiving in addition one per cent of cod-liver oil daily The second batch developed normally, but the first, even in those cases where the usual symptoms of rickets were absent, failed to develop even on subsequent exposure to sunlight Their skeletons were stunted and deformed, the breast bones being crooked —A D Delap, A Farrington, R Lloyd Praeger, and L Bouvier Smyth Report on the recent bog-flow at Glencullen, Co Mayo The chief points of interest about this bog-flow are (1) the fact that it occurred after a spell of dry weather, (2) the fact that a comparatively small area moved out of a very large area apparently similarly situated The bog slid from a site where the slope was about 3° into the valley of a stream and thence for several miles down the valley, the gradient of which is about 2°, at a considerable speed It is suggested that the bog was held in position by the vegetation on the surface and that this shrank and split owing to the drought The underlying layer was probably kept in a semi-liquid condition by the drainage from a small tarn on the crest of the hill just above the slide The total volume of the slide was about 400,000 cubic yards —H H Jeffcott The performance of a reservoir subjected to flood Simple graphical and tabular methods are given for finding the rise of the water above the sill of the spillway at any time owing to any assumed combination of rainfall and local circumstances This enables a spillway to be designed which will ensure the safety of the reservoir without an undue sacrifice of capacity —J Lyons and W Finlay The influence of heating and agitating milk before separation on the fat loss in skim milk Experiments carried out under the conditions prevailing in a working creamery show that the increased yield of fat caused by heating the milk before separation rises as the season advances Agitation always tends to reduce the fat separation, apparently by breaking up the clusters of fat globules It is doubtful whether in creameries of moderate size the amount of butter fat obtained by initial heating pays for the cost of the heating

### CRACOW

Polish Academy of Science and Letters, June 12 —St Mrozowski The hyperfine structure of the resonance line of mercury (2) This study, with experiments on the Zeeman effect, suggests that the components of the line 2537 Å are due to various isotopes of mercury —S Szczeniowski and L Infeld The effect produced by a cloud of electrons on the structure of the de Broglie wave In certain exceptional cases, the combined influence of the cloud of electrons and the crystal may result in an effect analogous with abnormal dispersion —Mile A Dorabalska Microcalorimetric measurements of the period of polonium The period of polonium determined by this method has been found to be 137.6 days  $\pm 0.4$  per cent —M Hlasko The differences between the conductivity coefficients of strong electrolytes in the same solvents —M Hlasko and W Klimowski The conductivity of certain mineral acids and the mobility of the hydrogen ion The mobility of the hydrogen ion, calculated from the limit of conductivity ( $\lambda_\infty$ ) of the acids HCl, HBr, HI, HNO<sub>3</sub>, and HClO<sub>4</sub> are (at 25°C) 355.0, 355.2, 355.1, 355.1, 355.1 —K Dziwoni-

ki, W Kahl, and Z Olszewski Study of compounds derived from naphthalic acid The synthesis of 3-4-dihydroxynaphthalic acid —E Mnich The phosphorus compounds of plants (6) The solubility of the phosphorus compounds of bean flour and the faculty of chytine of combining with the protein substances contained in this flour —Tymrakiewicz The stratigraphy of the peat bog situated near Dublany, Olesko, and Opaki The method of pollen analysis has been applied to these three peat bogs in the Haut Bug basin —J Jarocki and A Demianowicz The presence of a ponto-caspian amphipod, *Chaetogammarus tenellus*, in the waters of the Vistula —L Ejsmont The density of *Proshystera rossittensis* and *Tanarsia fedtschenkoi*, with some remarks on trematodes with nited cæca —J Hirschler Observations concerning the reciprocal influence of the larvæ of insects —Z Brodziński The development of the blood-vessels in the pectoral fin of fish belonging to the genus *Salmo* —Rogoziński Experimental rickets (3) The influence of ammonium chloride on the mineral metabolism of the rachitic rat No favourable effect is reduced by the addition of ammonium chloride to the Steenbock and Black diet

July 6 —L Lichtenstein Contribution to the study of partial differential equations of the elliptic type —Blaton The quantisation of atoms by a light wave —K Koziel The exactitude of the proposition of Laplace and Oriani relating to astronomical reaction —T Olczak Measurements of the acceleration of gravity in Poland in the period 1926–30 —Irene W Zablocka The fossil fungi of the Tertiary epoch in the rock salt mines at Wieliczka —Mme W Zablocka *Boletus parasiticus* and *Pisolithus arvensis* —A Demianowicz The terrestrial isopods of Bessarabia —Mile M Gasowska The cestodes of the birds in the neighbourhood of Kiev (Ukraine) —J Muszkowski Studies on the evolutive cycle and the structure of the maritime cestodes The larvæ of *Procotyle urna* —Mme B Konopacka The behaviour of the fat in the development of the embryo of the owl —St Smreczyński Embryological researches on the development of the head of *Salpica obscura*

## GENEVA

Society of Physics and Natural History, Nov 18 —Rossier The statistical distribution of the stars as a function of the type of spectrum (2) The statistical discussion of the complete collection of spectrum photographs of the Observatory of Geneva has led to a distribution of the stars practically identical with that which had been obtained from a selection of the series of plates —P Rossier The absolute colour index and stellar statistics. Application to the statistics of the Geneva Observatory The stellar statistics based on visual brightness show a proportion of less hot stars than that which would have been obtained if the eye had possessed the same sensibility for all wave-lengths For statistics of the hot stars the use of photographs seems to be indicated —G Tiercy A remark on the problem of comet orbits The author presents a note on the first equation of the problem (the equation of the trajectory), when the condition of visibility of the comet is taken into account This condition requires, as is known, that the perihelion distance should be below a certain limit

## ROME

Royal National Academy of the Lincei, June 21 —Vitali A result of F Hausdorff and the compressibility of matter —G A Crocco Aerodynamic bodies of negative resistance —L Labocchetta A new class of circular functions —T Viola Further work on the

dextro derivative of a function continuous towards the right and derivable towards the right —B Hostinský The integration of linear functional transformations. —G Krall Adiabatic transformations in systems vibrating within stable equilibrium configurations —E Segrè New Raman bands of water A new Raman band for water with its maximum at about  $140\text{ cm}^{-1}$  from the primary band is described This band is moderately intense on the low frequency side, but the anti-Stokes band is scarcely perceptible Its origin is attributed to oscillations in the polymerides of  $\text{H}_2\text{O}$ , the low frequency of oscillation being explainable by the appreciable mass of the oscillating parts and the tenuity of the linking This view is supported by photographs taken at temperatures ranging from  $4^\circ$  to  $97^\circ$  —N Apolloni Fauna of the bottom of the lagoon of Orbetello —C Cappelletti Resistance of the stolophyll of *Tulipa silvestris* L to the penetration of mycelia The inability of mycelia to penetrate this organ is to be attributed to the peculiar epidermic structure of the stolophyll, this excluding all infection, whether by micorrhiza or other more or less saprophytic mycelia of the microflora of the soil Owing to such protection, the plant assures to the bud a condition of absolute sterility, so that the symbiotic root life is to be regarded as a phenomenon subsequent to the development of new roots, and is not connected with any infection contracted by the mother plant

## India: The Real Problem.

THE course of events in India since the rising of the Round Table Conference in December last may well seem to confirm the opinion of those who held that little practical good was effected in the second session of that body, which lasted throughout the autumn. This view of the result of the conference was perhaps unduly pessimistic. The unexpected adherence of the Princes brought the question of an all-India federation within the range of practical discussion and even though the differences of Hindu, Sikh, and Moslem were not resolved, and the position of the Outcastes remains unsecured, goodwill and mutual understanding were advanced by discussion. This has been admitted by delegates on their return to India. But most significant of all, perhaps, was the final phase in which the Prime Minister seized the opportunity to make the momentous declaration on behalf of the National Government, afterwards embodied in the White Paper, that Great Britain would press forward towards measures of constitutional reform in India even though the Round Table Conference had produced no concrete proposals to meet the difficulties which stand in the way.

However strong may be the body of opinion, whether in Great Britain or in India, which doubts the wisdom of the grant of self-government to the greatest of our dependencies, the day for argument has long gone by. It is for this reason that much of the discussion on the White Paper in the debates in the two Houses of Parliament, admirable as it may have been from the constitutional point of view, seemed to be fatally out of touch with the needs of the situation, when it pressed for delay before endorsing the principles of the Prime Minister's pronouncement. The firm declaration of Great Britain's determination to go forward and the practical measure of the appointment of Committees to explore the ways to a solution of outstanding difficulties conveyed a much-needed message to the peoples of India as a whole.

This message stands in no danger of the misconception of weakness to which eastern peoples are prone in viewing a concession. The firm handling of the situation at the first sign of disorder on the return of Mr Gandhi to India and the action taken against the Indian Congress and kindred associations, as well as against the so-called 'Red-Shirts', opportunely accompanied as they were by a reaffirmation of the Government's intentions in the matter of constitutional reform, served to confirm the impression which it had evidently been the intention

of the Prime Minister to create. Granted a tactful and informed handling of the problems which must come under consideration in the near future, and the position of the Indian Congress should become untenable.

It must be borne in mind, in considering the situation as it stands to-day, that of late years in India a fundamental change has come about. This is due to the growth of what, for lack of a better term, may be called a 'national feeling', so far as such a thing can exist among so many diverse peoples. In dealing with the political problems of India we are no longer confronted, as was once the case, by the political agitator only, or even by one class alone, claiming on racial, social, or intellectual grounds a predominant share in the affairs of the State. The desire for change is spread over the whole area, almost without distinction of race, creed, or tongue. In parts, the rural population, which forms the largely preponderant majority of the peoples of India, crushed by economic conditions, often unable to earn even a bare subsistence owing to the fall in prices and the low value of silver, and crippled by debt and arrears of rent, would welcome alleviation of its troubles from almost any source. It has been persuaded that relief will come with political reform. The danger is that its only hope should be in the revolutionary nostrums of the political agitator and the suggested agrarian measures which the Indian Congress, aiming at usurping the functions of the Government, has formulated. This is the India, blindly seeking relief, to which Great Britain speaks. It is the India from which she has received loyal support in the past, and will once again if the present crisis brings forth anything like an adequate solution of social and economic difficulties. But it must be said that no solution will prove adequate which is not firmly based on intensive and scientific study of the racial and sociological factors which enter into the situation.

The difficulties with which we are confronted in India are to a great extent of our own making. It is true that they are not peculiar to India. They arise wherever an attempt is made to graft European political ideas and machinery on to the social concepts of the Oriental, as, for example, in China. The strength of our rule in India lay in the loyalty of the population, and particularly of the rural population, to the British *raj* as personified in the King-Emperor, just as the personal link with the emperor was the binding force in the Chinese empire. It is often stated—usually with some air of authority—that Orientals are best ruled by an

alien race. The saying has some justification, but it requires qualification. Where it has held good, acquiescence in an alien rule and loyalty to the ruler have been proportionate to the extent to which this rule has accorded with the ideas of the subject race—in other words, so long as the ruler has left their institutions and beliefs untouched. Notwithstanding many mistakes, this has been the basis of what, on the whole, has been our successful rule in India. But we have allowed loyalties to be diverted by political agitation so that now the people no longer accept an alien rule unquestioned even in the native States. In Kashmir, for example, the Moslem population voices its discontent against the Hindu princes whose rule it has endured for generations.

The twentieth century reaps what the nineteenth century has sown. Although the study of the languages, literature, and history of India made great strides in the nineteenth century, relatively little attention was paid to the living institutions of the people, outside those spheres in which they came into contact—it might almost be said into conflict—with the laws and regulations laid down by a European administration fundamentally from a western point of view and only gradually and slowly modified to any degree of conformity with the outlook of the Oriental mind. Such knowledge of custom and belief as was acquired by officials in the course of their duties—of necessity, they found, as an essential condition of dealing faithfully with the people under their jurisdiction—was uncoded, often lost, on their retirement, because unrecorded. The theories of Max Müller and Sir Henry Maine's studies of Indian institutions gave an impetus to ethnographical observation among the people and the record of their customs and beliefs which bore fruit in the studies of Crooke, Risley, and other workers in the latter part of the nineteenth century and the early years of the twentieth. But it was long before it was realised that these studies had any bearing upon the problems of administration, except by a few such as the late Sir Richard Temple, who had attained that knowledge empirically. It is doubtful how far even to-day it is realised how vital is the bearing of anthropological studies, not merely on the ephemeral difficulties of administrative routine, but also in the solution of the graver problems of the future of the rank and file of the Indian peoples which will arise under the altered conditions of India when, in greater or less degree, it is responsible for its own government.

Even had no other forces been at work, with

this failure to appreciate the significance of native institutions in view, it is not surprising that the development of the Indian has proceeded entirely on western lines, and that the only road open to him to progress in education, in the arts or sciences, in industry or commerce, and in political life has been directed solely towards European ideals. In consequence, advancement has been confined, broadly speaking, to the higher strata of the people, and that, too, of the urban classes. On the other hand, for the rural classes, who constitute the vast majority of the population, very little has been done by British rule to help them in any real progress towards a higher level of culture and an improved standard of life, which, it has been assumed, next to the preservation of law and order, it is the aim of good government of a people of backward culture to secure.

The more closely anthropologists study the conditions which arise when European ideas and culture come into contact with those of less highly civilised peoples, the more clearly it is appreciated that the harmful effect of the impact results from the break-up of the less advanced institutions and the emancipation of the peoples from their traditional controls. Native institutions need strengthening rather than weakening, while progress can most safely be promoted by a gradual modification of these institutions in directions which are in harmony with the temperament and genius of the people. The circumstances of India, combined with British policy, which, mainly, has been one of non-interference, on the whole have served to protect the rural population from this break-up of tradition, but there are signs of change. It is this rather than the agitation for constitutional reform that in the long run will call for every resource of skilful statesmanship.

It is dangerous to generalise in dealing with a country of so many races, creeds, and languages and so many variations in degree of culture as lie within the bounds of India. One generalisation may be made, however, with moderate assurance, and that is that the one stable political factor is the village-community. Whatever may be the type and the organisation of the village-community—and the variation is indeed wide—the social consciousness of its members finds expression, not as individuals, but as parts of a unitary organisation in which each individual has a recognised grading and a voice carrying more or less weight in the settlement of communal affairs. To a communistic mentality at home in this environment, the franchise, the supreme, and, indeed, the only expression

of political individuality open to modern democracy, offers little that is comprehensible. Unless self-government in India is to become a pretence and an oligarchy in the hands of a section representing at most perhaps a tenth of the population, the problem of India lies in the development of the village-community and the mentality of its members on lines which will lead eventually to real self-government through the representation which at present lies outside their experience or even comprehension. This is a problem to which either the Committee on the Franchise or the Central Advisory Committee now set up might well direct their attention. But it may not be out of place to suggest that the skilled advice of those who have studied closely village-community organisation from the anthropological point of view should be sought. Modification of such institutions without full knowledge of their content or meaning in the life of the people has been shown by experience too often to bring disaster.

In Burma, by the reservation of the Shan States as a backward area, the reformed Government is to be relieved of the problem of its less advanced compatriots. In India it looks as if we shall pass over this problem to the governments which will succeed us. In any event, whether it should be found possible or not to develop the political sense of the people through their existing institutions, the portents are that an even greater understanding of them, such as comes from trained study on anthropological lines, will be required of the administrators of the future. This holds good in no less degree because those from whom such understanding will be demanded in days to come will be natives of India rather than Europeans. This is one of the reasons which weighs with those who think that the trend in the past has been towards the too thorough Europeanisation of the educated native of India. But to suggest that Indian education needs a new orientation towards the art, culture, history, and economics, as well as the natural history and geography of its own country and peoples, opens up a question upon which we must not dwell at this moment. For the present purpose it must suffice to point out that such a change in orientation is an inevitable and necessary condition of success in the self-government on which India is bent. Experience confirms the view of common sense that the high-class educated native of India is no more capable than the European of comprehending without close study India's infinite variety of language, race, and culture.

### Back to the Land.

*Rediscovering England* By Charlotte A Simpson  
Pp 360 (London Ernest Benn, Ltd, 1931)  
21s net

BACK we must and without delay This book has an arresting value as a meritorious and attractive attempt to develop and encourage an interest in the countryside, now fast being buried in bungalows, tarmac, petrol pumps and pill signs, its matchless beauty by-passed out of existence everywhere, even in far Glencoe, the life-blood of its once majestic trees drained away to river and sea (seen in Greenwich Park and infested elm areas), incidentally, the phosphates are sent awash. A couple of thousand years hence, perhaps, England will be rediscovered and disinterred, like Herculaneum, by its curious Mongolian possessors, who will write books, like Flinders Petrie's, in which they discuss the overwhelming evidence they have found of a once glorious civilisation becoming rapidly decadent, owing to the introduction of a debased religion, which had led to the entire neglect of the natural and the worship of brazened gods called machines. This, at the hands of a selfish, commercialised priesthood of engine-makers, working to enslave man and make him unnecessary, burying him in the pit and the town and binding him to rivers of water and of oil, instead of inspiring him to fall down upon and worship the soil from which alone he comes and can gain sustenance.

England has not yet even been discovered by the schools nor any proper desire to know it implanted in their pupils. Since cycling came in, boys and girls have learnt to read maps and cleverly use them in rushing about—to no other end. The 'muddled oaf' on cricket or football field knows clay only as dirt. In days gone by I have tested hundreds of them from public schools and found scarce one who had learnt more than that you slip upon it.

For in the Market-place, one Dusk of Day,  
I watch'd the Potter thumping his wet clay,  
And with its all obliterated Tongue  
It murmur'd—"Gently, Brother, gently, pray!"

We thump it with plough and upon potter's wheel without thought. Now "its all obliterated Tongue" must be tended and healed, made vocal to us all. That we should only take interest in it when flung into ever-receding space in nebula and star is preposterous. As geologists cannot get us gold enough, they might well take up such lesser things and seek to make their value more plain.

Who cares to know the make-up of 'Our Realm of Albion'—how many can give an intelligent interpretation of the phrase and locate Albion-stuff?

In the school of to-morrow, when education is thought of as a preparation for life, not for an examination, maybe an arrangement will be made with the local Office of Works for the supply, at arranged intervals, of a few cartloads of road making or building material, together with gravel, sand and clay. These will be dumped in the playground and thoroughly studied. The various hard rocks will be supplied in big pieces needing to be broken to gauge. Children will have an opportunity to learn what stone-breaking involves and what the feel of stones is. Clay, loam and sand will be dug over and handled. Frequent visits will be paid to local exposures. Bricks will be made. Limestone will be burnt to lime, this slaked, made into mortar and a wall built. Various rocks will also be studied in the school workshop, not in the superficial way that is now customary but measured and weighed so far as is necessary to establish their individual characters. Sections will be cut and examined under the microscope, stones will be polished and worn. The classroom will be used mainly for discussions and in writing considered accounts of the work, in amplification of notes taken while it is in progress. In this way, English will be taught by the Squeers method after all the only sane method. Unless instruction of this order be given in the near future, no God will be found to save us.

We have less to consider what is in Miss Simpson's book than the vision it calls up of the vasty deep of ignorance before us, of what might be and what should be in the now empty pates of those who scorch—or even hike—through our highways and byways. Hiking is sure good for the muscles and lungs—what of the soul? We wonder what the average talk of the hiker is—the proportion of 'eyes' to 'no eyes'.

The authoress—it is a mistake to speak of a woman writer as 'author', the words are not synonymous—is lecturer in geography at Warrington Training College, Liverpool. Her book is welcome evidence that the teaching of the subject is at last coming into enlightened hands and tinged with geology. Although geology is the one and only possible foundation of a true geography, the subject is scarcely if ever mentioned in most schools. Where taught, it is taught apart and mostly at the desk. Years ago, visiting a noted school, which

professed to teach geology and gave the subject its room, injudiciously inquiring what sections in the district—one rich in outstanding examples—had been visited, I discovered that it was only a four-wall subject. I have never ‘acquired merit’ in my own estimation so much as when I was able to couple geology with geography upon the first plans for the recently erected extension of the science buildings at Christ’s Hospital School. The two names now appear together upon several classroom doors. Has such happening ever been before? Still, I doubt if I shall live to see the children swarming about my heaps o’ stones in the yard and the teacher with the *nous* and enthusiasm to conduct the worship, I say children, because such work must be begun in the preparatory school and ever afterwards continued.

A true geography is now coming upon us, through the enlightened enterprise of the railway companies and also through the publication of often most admirable large scale reproductions of photographs in the press, especially the *Times*, which is setting a great example. One of the first, if not the first, of the magnificent half-page pictures published in that journal, was that of the southern end of the Jaws of Borrowdale, which I had sent to them at the time when we were trying to prevent the desecration of the valley by the soulless engineer on behalf of the road-hog, unfortunately, without effect. The memorial ‘mutton-back’ we desired to save from further injury is figured by Miss Simpson, as it was before the snout was wickedly blasted away.

The pictures we now get in the press are some consolation. Yet they are apt to be misleading, though good in form, owing to the vagaries of the modern over-corrected photographic plate, which now has a nasty trick of rendering yellow and red in white. This distortion was specially noticeable in the striking picture of the Sidmouth coast published in the *Times* of Oct 24. Perfect in outline and as a panorama, the entire stretch of coast appeared white as if it were chalk. Actually, only the far-distant corner, Bere Head, is Chalk rock, the rest is a deep red, capped by yellow Greensand and a final, scarcely perceptible thin layer of chalk east of Sidmouth. The Southern Railway displays a magnificent poster of South Devon, giving the true appearance of the red rocks, in another, the junction of the chalk with the New Red beds is strikingly shown.

The photographer of coast scenery to-day needs to have the geologist’s eye and must choose light, plate and screen with considered care. An in-

valuable series of posters is now being produced by the railway artists, showing that they are most accurate observers not only of form but also of geological character as shown by colour. At the recent Faraday Exhibition, at the Albert Hall, as one illustration of the use now being made of colours derived from Faraday’s benzene as printing inks, at ‘The Sign of the Hexagon’, a particularly fine series of posters was arranged along 36 feet of the screen at the back of the stand, showing how geology may now be studied *from the railway platform* colour chemistry, too, if you will.

No school should be without these posters, it would be to the advantage of the railways to put themselves in communication with the schools, so as to provide these regularly with appropriate issues. The Empire Marketing Board might join in the game. Foreign posters might be included though often flamboyant and misleading in colour, these are faithful in form and very attractive. If children saw posters at school, the question ‘where to go in the holidays’ might often be answered with intelligence—not so frequently from the Lido point of view, perhaps, though some companies seem to favour the display of muscular femininity rather than of scenic beauty.

Consider the effect of using the railway posters systematically. We have quantities of sand everywhere upon our island shores, upon which spade and pail are most deftly used by multitudinous young urchins during the holidays. The children are patently full of an inquisitive intelligence, yet when they go to school they take no further interest in the material which we are told forms at least 60 per cent of the crust of our earth. I have suggested above a way of continuing the spade drill, the pail should also not be forgotten. Picture the joy many youngsters would have in helping to boil down pailfuls of sea water and extracting the salts systematically. The discovery that there are so many different things in sea water is itself a revelation. Suppose the study of sand and sea were thus quietly continued at school, young people might go to the seaside not only with minds but with minds really prepared to find “sermons in stones”—an art that has made little popular progress since melancholy Jacques advocated its practice notwithstanding the money lavished upon our schools and the attention nominally given to Shakespeare.

The mental vacuity of the average seashider is delightfully pictured in “A Fortnight in September” by R. C. Sherriff, though reflection falls upon the literary interpreter in putting no high lights into

his picture Surely there are thrills to be got out of the rocks Are the word purveyors, the Aldous Huxleys, ever to wander in realms of merely euphonious expression? Will they not learn something of Nature outside man and lead him to see that he may sometimes adventure with profit away from himself Have their forefathers lived to so little purpose that they have no care for real culture? The broad culture that I heard Huxley advocate, full fifty years ago at Birmingham, is no more come upon us to-day than it was then—the literary mind seems to be ascientific, in the Huxley sense it lives only in the hlt of words so, the sooner we decide to depose it from our schools the better down to Nature, back to the land, we must in some way go We must learn to lime our souls as well as our soils "Lime!" I hear the young Huxley say, "What is lime?"—as if it were a carminative! He inherits no interest in it

Miss Simpson would make geo-topography—not geology—the key-note to the development of the countryside Unfortunately, she flings only scraps of geology at her readers Most will have no fundamental earth-knowledge It is this fundamental training that is so necessary and so lacking to-day Rocks must have been hammered off and handled sections visited and photographed the nature and worth of fossils and of stratigraphical relations, the character of soil, realised There must be clear elementary understanding of the chemical nature of sedimentary and igneous rocks It is pleasant enough to speculate why this village is on the hilltop, that in the valley below this, however, leads nowhere

Our business to-day is to understand the ground upon which we live, sufficiently to use it to the general good, we need to extend our view to the Empire, if we are to avoid making endless mistakes Some day Australia must awaken to the importance of the study and see how much of the land is not habitable

Far too much is attempted The book is one to be read with interest and profit but not as a guide to methodical study in fact, as in all our attempts at didactic, scientific writing, the intellectual process is in no way made clear that we aim at developing by observational and experimental study The illustrations are exceptionally good and sometimes really beautiful—that of the Stroud valley from Burleigh, for example It is a pity the authoress does not give us more of her own work—the example at p 151, 'A Cotswold Barn', is definitely a work of art

The book is also full of literary charm—though this side is a little overdone Still, to have brought "Defoe's Tour through Great Britain" to the fore is no slight service Strange to say, Charles Kingsley's "Lectures on Town Geology" nowhere finds mention it is the one book into which method enters, the book of scientific essays in which it appears should be studied by every teacher of geography The use made of the pictures is sometimes far from what it might be, if not misleading On p 189, for example, a photograph is reproduced of Grange, Cumberland, showing the bridge over the Derwent at the foot of Borrowdale it is one of the best of its kind I have ever seen The reference (to glaciated country) is as follows —

"The most casual visitor and lover of scenery will notice the boulders of different shapes and sizes scattered over the hillsides, obviously brought from a distance and dropped there by some means which no longer exists Also many rocks partly embedded in grass or bracken have their surfaces rounded and smoothed as if by something of the nature of sandpaper passing over them One of these is shown in Fig 32, between the village and the bridge"

'Grange is conspicuously free from scattered boulders The rock referred to, just behind the bridge, at the far end adjoining the cottage, is noted among geologists It is part of the general rock mass, not an embedded rock glaciated over the whole of its surface, down to its base below water in the shallow stream, it is clear evidence that the rocky river bed has remained unworn and unaltered in level since the Ice Age, whenever that may have been Unique in its way, it should be scheduled as a national monument, so that it may be protected against any and all future disturbance.

In adding, in a pocket, a copy of the Geological Survey map, beyond question the most wonderful map in existence, Miss Simpson has done notable service

Whatever the shortcomings, the book is to be commended as a whole-hearted attempt to further the study of a neglected and undeveloped subject In making an appeal to headmasters, thirty years ago, I quoted words used by Matthew Arnold —

"The want of the idea of Science, of systematic knowledge is the capital want of English education and of English life"

He would say this to-day, if with us We have still to follow the advice he gave in 1886 in saying—"the ideal of a general liberal training is to carry us to a knowledge of ourselves and the world"

This is geography *in excelsis*—in its every mood and tense, a subject as yet unrecognised in the

schools Our architects to-day have so little æsthetic feeling, they are so rigid in their outlook, that in the buildings they erect, talk is becoming a mere clatter of noise modern building involves rejection of the brick and of the human hand and is soulless in its lack of softness, even the mortar is a hard synthetic cement In like manner, the 'science' of the schools is mere clatter of noise Having done so much to paint our globe red, it is time that we took up the serious study of at least the reddened areas if we do not, we may easily lose both them and ourselves

HENRY E ARMSTRONG

### The Constitution of the Human Body.

*The Physical Basis of Personality* By Prof Charles R Stockard Pp 320 (London George Allen and Unwin, Ltd, 1931) 12s 6d net

ALTHOUGH Dr Charles Stockard, professor of human anatomy in Cornell University, has given the title "The Physical Basis of Personality" to the book under review, it is in reality an important contribution to our knowledge of the physiological and developmental processes concerned in the shaping of the human body Under the action of these processes human types are moulded, and new races and species are ultimately produced The author explores the machinery of evolution from a new angle His primary purpose is to explain, not the resemblances which link one man to another, but the differences which distinguish every individual born into the world from all other births—past, present, and future It is an explanation of the 'uniqueness' of every birth and of the manner by which every human being comes by his or her 'individuality', 'personality', or 'constitution' that is Prof Stockard's quest

Prof Stockard's search carries him first to the 'physical basis of heredity'—the chromosomes of the fertilised egg He reads into the human egg what has been learned from the egg of the fruit fly—*Drosophila* Personality, he holds, is determined as soon as the chromosomal constituents of the male and female elements have become assorted in the fertilised ovum He then turns to experimental embryology to discover how the qualities inherent in the chromosomes of the fertilised egg become manifest or are 'expressed' during the earlier stages of development He comes to the conclusion that although the basis of personality is already present in the egg, yet the expression of all

the potentialities depends on 'environment', particularly on the 'internal environment', which in the case of the embryo is the fluid by which its cells are bathed and nourished Prof Spemann's researches have thrown a flood of light on the nature of the internal environment The tissue fluids of the embryo are charged with substances which act as 'organisers' From fertilisation to death in old age the internal environment is ever changing, hence 'personality' is never fixed, it alters in every decade from childhood to adolescence and from adolescence to serene old age Prof Stockard concludes that the personality of every man and woman is determined by the interplay between their chromosomal potentialities and the environment which these potentialities meet with when seeking for expression External environment is effective only when it can alter the internal environment and constitution of the individual

The best parts of this book are based on investigations carried out by the author himself Prof Stockard was bred in the orthodox school of reconstructional embryology and continued in the straight anatomical path until 1907, when he had his first lapse into experimental embryology By hatching eggs of the minnow in sea-water, to which he had added a certain percentage of a magnesium salt, he produced one-eyed and other monstrous forms He was thus made to realise the importance of internal environment After a brief interlude spent on the study of regenerating tissues, he again resumed his inquiries into the influence of internal environment Alcohol was the agent he selected for experimental study He subjected guinea-pigs, generation after generation, to an over-dosage of alcohol, to ascertain whether or not their germ-plasm was thus damaged Although in the earlier generations there was a high mortality of the young within the uterus, the ultimate result of the experiment was the production of guinea-pigs as sound as the original breed He then resumed his studies in experimental embryology, amplifying and exemplifying Wilhelm Roux's conception of the 'struggle for expression' which goes on between the developing parts of an embryo

Then, in 1921, Prof Stockard struck into another field of inquiry, and obtained results which form a large part of his present book He became interested in the tissue fluids—the 'internal environment'—not of the embryo and foetus, but of the growing child and matured adult. Starling's demonstration that growth-controlling substances—hormones—circulate in the tissue fluids, and the belief, acted on by medical men, that growth

disorders of the human body are brought about by a break-down in the normal interplay of the glands of internal secretion, led Prof Stockard to seek for means of putting these beliefs to the test of experiment. The breeds of domesticated dogs seemed to offer ideal opportunities for his purpose. Dog fanciers, quite unconsciously, have exploited the growth-controlling or hormonal systems of the body to produce the various known breeds. Prof Stockard regards the Irish wolfhound as the plain (non-acromegalic) form of canine giant, the bloodhound and St Bernard show the features met with in human acromegalic giants, the mastiff has the qualities of simple acromegaly, toy breeds are canine counterparts of human dwarf-midgets. The British bull-dog, the dachshund and the griffin reproduce the various forms of achondroplasia met with in all races of mankind. To exploit this new field Prof Stockard found it necessary to add to his anatomical department a farm for experimental morphology.

It is not necessary to review the results which Prof Stockard has obtained at his farm. Two matters, however, are too important to be passed over. He has found that there are exceptions to Dollo's law of the irreversibility of evolution. He has succeeded in bringing back, to the feet of guinea-pigs and dogs, digits which were supposed to have disappeared for good. The 'genes' responsible for the missing digits must still be latent in the germinal chromosomes. He finds, further, that growth control involves two factors—a local factor inherent in the organ or part, and a circulating factor, a hormone. Further, however much the internal environment may be changed, the inherited influences, conveyed through the germinal chromosomes, are dominant in determining the form of growth. In this connexion, however, it must be remembered that the 'organisers' of the embryonic body and the hormones of the growing child are also the results of influences which are transmitted through the chromosomes of the fertilised ovum.

There is one important contribution added to our knowledge of evolution since Prof Stockard wrote this book, which will certainly lead him to modify one of his statements. He accepts the conclusion reached by Sir Francis Galton namely, that "all families and stocks have a strong tendency to return to the mean of human ability, mediocrity." If this were really true, it is difficult to conceive how the evolution of a new type or of a new species would ever have taken place. Prof Karl Pearson has proved (*Annals of Eugenics*, 1930, vol 4, p 1)

that in an isolated community, of any kind of living things, the tendency is not to return to mediocrity, but for the qualities with which the community was originally endowed to become ever more intensified. Prof Stockard's own experiments seem to support the law of Pearson rather than that of Galton.

Prof Stockard is a human anatomist of a new kind. He seeks to unravel the problems of morphology by an appeal, not to the dead, but to the living body. His "Physical Basis of Personality" must be recognised as one of the most important contributions which has been made in recent years to our knowledge of the biological processes concerned in the evolution of humanity.

A KEITH

### The Metallic State.

*The Metallic State Electrical Properties and Theories* By Dr W Hume-Rothery Pp xx + 372 (Oxford Clarendon Press, London Oxford University Press, 1931) 25s net

IT becomes increasingly difficult to-day to work contentedly at any one corner of knowledge, unrecking of the repercussions between the different branches of science, moreover there exist borderline regions, the successful cultivation of which demands an intimate acquaintance with the facts and theories of two or three branches of science. At the same time it is not easy to take a catholic view—the enormous mass of accumulated facts, increasing in a manner which reminds one of the expanding universe, drives us, in despair of ever coping with them, back to the position of the specialist, cultivating our corner, perhaps not so contentedly, as we muse upon the inter-relations which we are perforce ignoring.

Metallurgy, and the relevant parts of physics and chemistry, exhibit very markedly the confusions and difficulties which arise from this lack of collaboration. As Dr Hume-Rothery points out, the practical metallurgist, interested in the properties of metals of commercial importance, has amassed a large amount of information which is not, however, seen against a background of general principles, and in particular has not been correlated with the regularities of the periodic table. The physicist, who has made most precise measurements of the thermal, electrical and elastic properties of metals, has not merely ignored the periodic table, but, "out of touch with scientific metallurgy", has carried out "much experimental work of the highest quality on specimens

which any scientific metallurgist would have condemned as unsuitable."

All the more grateful should we be to him who, possessing the necessary qualities of detailed knowledge and philosophic breadth of view, essays this task of correlation and carries it to a successful conclusion, as Dr Hume-Rothery has certainly done. He is at once encyclopædic and eclectic, encyclopædic, inasmuch as, even where little information is available in the book, he provides us with 'pointers' which serve to show where that information may be gained, eclectic, in that he chooses for detailed description certain parts which presumably are most to his personal taste, as they are obviously written *con amore*. It must be confessed that he has, for the most part, chosen well and wisely.

The book is divided into two sections—the first section dealing with the experimental facts, the second with the various theories that have, from time to time, been propounded to correlate these facts. Detailed discussion of experimental technique very properly finds no place in Dr Hume-Rothery's scheme, none the less, as we have just remarked, he gives ample references for those who wish to study experimental methods. The first section, which occupies rather less than half the book, contains chapters dealing with the electrical conductivities of pure metals, primary metallic solid solutions, secondary solid solutions and inter-metallic compounds. The facts dealing with the effect on resistance of temperature, pressure, and of stress and deformation are very fully and clearly stated, and space is found for a fairly detailed account of galvano- and thermo-magnetic effects. The thermal conductivities of pure metals and of alloys are next discussed, and the effects of temperature, pressure and deformation are described. Chapters on thermo-electric properties, emission phenomena and contact electricity complete this section.

It will be seen that Dr Hume-Rothery has omitted all consideration of the facts connected with specific heats. The omission is deliberate, inasmuch as "these are dealt with in most books on Physical Chemistry." But similar remarks may be made concerning most of the sections with which Dr Hume-Rothery has dealt. After all, it is the angle of outlook that matters, and we trust that, in the next edition of his book, the author will reverse this decision, and will give us a résumé of specific heat results as clear as those dealing with the properties just mentioned.

It is pleasant to note that, in a book which

carries us to the confines of existing knowledge on the subject, Dr Hume-Rothery, with the instinct of a teacher, is not afraid to begin at the beginning. Thus his chapter on thermo-electric properties begins with an admirably simple discussion of the fundamental phenomena, which may be read with profit by the general student. Concerning this discussion, attention may be directed to one point which is commonly overlooked in the elementary thermodynamic treatment of the matter. The thermo-electric electromotive force  $E$  is a property of the whole circuit. If now we attempt to establish the equations of the circuit by assuming that the cold junction is kept at a constant temperature  $T_0$ , and that the hot junction, originally at  $T$ , is raised to  $T + \delta T$ , the differential coefficient  $\delta E / \delta T$  is certainly not a property of the whole circuit. The point is subtle, and neglect of it has given rise to considerable confusion. The whole matter was very fully discussed by Prof A W Porter in his presidential address to Section A at the Glasgow meeting of the British Association.

In the second portion of the volume Dr Hume-Rothery has been faced with a task of more than ordinary difficulty. Here again he has resolved it by beginning at the beginning, a method which, although it involves a certain amount of repetition and of discussion of discarded theories, is more likely to beguile the reader up the steep slopes, "with learning put lightly, like powder in jam", than is the opposed process, not uncommon nowadays, of plunging him "directly into the strange conceptions which are resulting from the new quantum mechanics."

In this section, then, the first chapter deals with Drude's simple free electron-gas theory, the second with the older complex gas electron theories. Chap III gives a brief conspectus of certain 'intermediate' theories, including Thomson's di-pole theory, and the theories of Wien and Gruneisen, of Bridgman and of Hall. Chap IV is concerned with Lindemann's electron-lattice theory, and Chap V with the Sommerfeld theory. The concluding chapter contains, *inter alia*, an admirable section on the periodic classification, and in an appendix is given what is, in effect, a translation of Bloch's paper of 1929, in which the motion of the free conductivity electrons is supposed to be a motion in a periodic field of force of period that of the atomic lattice.

Dr Hume-Rothery has given us a thoughtful and well-ordered survey of a more than ordinarily difficult region. His book may be unreservedly commended.

ALLAN FERGUSON

## Short Reviews.

*Air Ministry Meteorological Office British Rainfall, 1930 the Seventieth Annual Volume of the British Rainfall Organization Report on the Distribution of Rain in Space and Time over the British Isles during the Year 1930 as recorded by over 5000 Observers in Great Britain and Ireland* (M O 335) Issued by the Authority of the Meteorological Committee Pp xix + 292 (London H M Stationery Office, 1931) 15s net

THIS volume contains maps, tables, and descriptive matter in the usual form, together with special articles on the exposure and shielding of rain-gauges at Penrith and Hythe, on measurements of wind velocity at the level of a rain-gauge, on the Jardi rate-of-rainfall recorder, and on cloudbursts on Stanmore in Westmorland.

For the British Isles as a whole, the rainfall of 1930 was 115 per cent of the average, the year being the eighth wet one in succession, though over a small part, including the Thames Valley, it was drier than usual. There are two outstanding events to note. One was the sustained torrential rainstorm on July 20-23, when 11.97 inches was recorded at Castleton, near Whitby, in Yorkshire, resulting in great damage to bridges in the valleys of the Esk and Leven. In regard to this storm, the geographical reader will not be pleased to see the country behind Whitby repeatedly referred to as the Wolds instead of the Moors. The Wolds, terminating in Flamborough Head, are the most northerly extension of the English Chalk system, and are separated by the Vale of Pickering from the very different country formed of the Jurassic rocks to which the North Yorkshire Moors belong.

The other event was the cloudburst in Westmorland on June 18. On this day, when violent thunderstorms were fairly widespread, there broke over Stanmore Forest, at the southern extremity of the Cross Fell range, one of those formidable storms of the 'cloudburst' type which, as records show, are relatively common on the high fells of northern England. Peat was removed from several acres of moorland, leaving deep scars on the hillside the debris causing quantities of fish to be suffocated lower down in the River Eden. Mr F. Hudleston, who describes the occurrence, says that the moors appeared to lie under a sheet of water and that something in the nature of a water-spout, from the sudden collapse of a heavily charged cloud, must have developed over Knipe Moor, where the holes were dug out.

L C W B

*Die tierischen Schädlinge des Ackerbaues* Von Sofie Rostrup und Prof. Dr. Mathias Thomsen. Nach der vierten dänischen Auflage ins Deutsche übertragen und für die deutschen Verhältnisse bearbeitet von Dr. H. Bremer und Dr. R. Langenbuch. Pp xi + 367 (Berlin Paul Parey, 1931) 18 gold marks.

THIS well-produced book, dealing with the animal pests of agricultural crops, forms a thoroughly reliable and up-to-date manual on the subject. It is

a German translation of the fourth Danish edition of the same authors' "Vort Landbrugs Skadedyr" (1928), with certain additions and amplifications in order to adapt it to German needs. The number of illustrations has also been increased. Although specially written for continental readers, this book will be found to include very few pests that are not concerned with some form of crop injury in Britain. It is, therefore, a volume which can be consulted with profit by workers and students in Great Britain. The bulk of the letterpress is, naturally, devoted to destructive insects, and other arthropods, but there are also chapters dealing with Nematoda, Chaetopoda, and Mollusca.

The method adopted is to treat of the individual pests by the orders or groups to which they belong. Each species is briefly but concisely described, its biology is discussed, and standard control measures explained. These accounts are clearly written in a terse style and most of the species dealt with are very well illustrated, with figures portraying the characteristic injuries they inflict. At the end of the book there is a tabular summary of the different pests arranged upon a crop basis. As a kind of appendix there is a short, but useful catalogue of modern literature classified under the names of the pests concerned. All concerned in the production of this volume are to be congratulated upon its general excellence.

A D I

*The Official Year-Book of the Scientific and Learned Societies of Great Britain and Ireland a Record of the Work done in Science, Literature and Art during the Session 1930-1931 by numerous Societies and Government Institutions* Compiled from Official Sources. Forty-eighth Annual Issue. Pp vii + 171 (London Charles Griffin and Co., Ltd., 1931) 10s net.

THIS valuable annual consists of a classified collection of the names and addresses of learned societies, with information as to officers, conditions of membership, meetings, publications, etc., and particulars of scientific institutions controlled by Government in the British Isles. Where publications are of the nature of reports on specific subjects or special lectures, the titles are in many cases given. Brief accounts of the history and work of certain institutions are also included. The information printed is provided by officials of the bodies concerned.

In the course of the forty-seven years of its existence, the "Year-Book" has grown, and last year the publishers announced that they proposed to economise by omitting lists of papers read before societies. This has been done in the present issue, and in consequence the subtitle should have been revised. That the change has made a substantial difference is evidenced by the fact that the volume is less than half the size of last year's issue and that the price is also substantially less. We believe that the volume in its new and abbreviated form will be welcomed, with few regrets for the omissions, and we are grateful to the publishers for retaining the characteristic and substantial binding.

## Field Anthropology in Central Australia.

THE continued opening up of the central regions of the Australian continent is rapidly diminishing the opportunities for carrying out research on living Australian aborigines under their natural conditions.

The Board for Anthropological Research of the University of Adelaide has, for a number of years,

FIG. 1.—A typical bush native. Note the scars on his thigh, and the hairstring around his head, arm, and waist.

organised annual expeditions to obtain information on various aspects of aboriginal life, but concentrating more particularly on physical and physiological anthropology. The expenses of these investigations have been met, for the greater part, by funds generously placed at the disposal of the Australian National Research Council by the Rockefeller Foundation for such purposes.

The time available for this work is limited to the University vacations, falling in the more temperate seasons of the year, and it has been found that, for short periods, the most efficient and economical method of securing the desired information is by means of team work. By this method, the personnel consists of men experienced in the proposed sections of work, each worker concentrating intensively on his own special province of research. By standardisation of the work and methods of observation a considerable mass of data is recorded in a relatively short time.

No. 3247, Vol. 129]

There was an expedition in August 1931 to Cockatoo Creek, situated about 185 miles northwest of Alice Springs in Central Australia. As in several previous and similar expeditions, the South Australian Museum co-operated with the University, and its representatives directed their attention to work in which they were specifically interested.

The party journeyed from the rail terminus at Alice Springs, about a thousand miles north of Adelaide, by motor transport, consisting of two motor trucks and two cars, and a further two hundred miles over the mulga plains and dry, sandy watercourses typical of such regions.

A field camp was established at Cockatoo Creek, nearly forty miles west of the areas as yet occupied by Europeans. At this site approximately one hundred and fifty natives were collected. They mainly represented the Ilpirra, Anmatjera, and Ngalia tribes. With very few exceptions, practically all these natives examined are still living their customary nomadic existence, and are entirely de-

FIG. 2.—The principals in a kwatja or water ceremony.

pendent on their own resources; thus they formed admirable material for scientific study.

In commencing these investigations each native was allotted a number; in most cases on the recent trip it was necessary to mark them with the numeral in cellulose paint, owing to the absence of any sort of clothing. The following list gives an idea of the

FIG. 3.—Performers in the tjilpa, a native cat ceremony.

scientific programme and the extent of the work carried out:

Genealogical data were recorded on ninety individuals. On fifty natives, routine anthropometric and descriptive anatomical observations were made. Standard photographs were taken of each individual.

The hair tracts of twenty-four children were charted. Other physical data such as skin creases, dermatoglyphs, spinal curves, and foot outlines, were secured on approximately forty individuals.

Blood grouping, entailing, with cross testing, about a thousand observations, was made on ninety natives. These results showed that sixty-four belonged to group A and twenty-six to group O.

The basal metabolism was estimated on forty-two individuals, and these, with associated tests on blood pressure, pulse, and respiration rates, etc., have produced some extremely interesting data.

On groups of individuals, varying from twenty-five to fifty in number, tests were carried out on the special senses, such as visual and auditory acuity; pain tests, strength tests, and special perception and intelligence tests were also made.

Excellent plaster casts were obtained of the faces of seventeen

natives, and also of scarred chests, of hands and feet, and of special anatomical features.

A considerable quantity of general ethnological data and photographs was secured on native customs, ceremonies, arts and crafts, as well as a valuable collection of native objects.

A vocabulary of approximately three hundred words was taken down, and native songs were recorded on phonograph cylinders. Cinematograph records were taken on both standard width and 16 mm. films, a certain amount of the latter being on natural colour film.

Although the natives were entirely uncivilised, no difficulty was experienced in obtaining their complete confidence and co-operation, a very interesting factor when it is considered that a number of the procedures, such as the routine of basal metabolism, the taking of plaster casts of the face, and the drawing of blood for blood grouping, might easily be expected to cause fear, resentment, or suspicion.

This expedition has been probably the most successful and fruitful venture that has yet been carried out in investigating the biological aspects of Australian aboriginal anthropology. The detailed results of the work will be published in due course.

### Genesis of Ores in Relation to Petrographic Processes.

THE development of theories of ore genesis since their discussion at the British Association meeting in 1833 was briefly referred to in his presidential address to Section C (Geology) by Prof. J. W. Gregory. He remarked that the belief in the deep-seated origin of ores had been at one time superseded by their assignment to lateral secretion and later to the igneous rocks. He assigned the source of the lode metals to a deep-

seated zone below the level of the ordinary igneous rocks, and regarded the occasional occurrences of lode metals in them as secondary. The trend of the discussion in the Geological Section on Sept. 29 supported these views.

The conference had the advantage of being opened by Prof. G. C. Cullis, who gave a luminous exposition of the formation of ore deposits by the segregation of the more valuable metals into local

concentrations. The processes may be classified, as with rocks, into the sedimentary, of which the ore products except of iron, are relatively insignificant; the metamorphic, which are comparatively unimportant; and the igneous, which exceed the others in economic value. Prof. Cullis regards the segregation of the ores in igneous rocks as an extreme development of magmatic differentiation, and he explained the process as in most cases due to hydrothermal solutions forming mineral veins. He remarked in conclusion that although there is now a general approximation as to ore formation in the petrogenic scheme, agreement has not been reached as to the actual process of mineralisation in any one of the main metalliferous fields. This paper is being published in the Report of the Association.

Prof. P. Niggli, of Zurich, dealt mainly with metamorphic ores, as so large a measure of agreement has been reached regarding the two other groups. The magmatic ores he classified into three sections: the orthomagmatic, those formed during the main consolidation of the igneous rock; the pegmatitic-pneumatolytic, those due to volatile constituents at high temperatures; and the hydrothermal, those deposited by aqueous solutions, exhalations, thermal waters, etc. The second main group or sedimentary ores are concentrations of matter derived by the weathering of rocks, whether deposited mechanically or by solution. They are sometimes influenced by epi-metamorphism, as with the gold deposits of the Witwatersrand, which in his opinion are undoubtedly sedimentary placer deposits. He described the metamorphic ore-deposits as often characterised by a profusion of rare minerals, such as the two hundred species at the Langban mine in Sweden, more than a hundred species at the Franklin Furnace mine, New Jersey, and the varied sulpho-salts of Langenbeck in the Binnental. Remarkable mine structures are due to dislocation metamorphism, as at Rammelsberg in the Harz, and he suggests as possible examples the pyritic masses of Rio Tinto and similar deposits. The character of these ores is often due to their mechanical deformation and recrystallisation during rock metamorphism. The poverty of ores in the central Alps is due to the magmatic solutions being barred in their ascent. He urged in conclusion that the study of ore genesis is the starting-point for the estimation of the world's reserve of minerals and for the framing of future economic policy.

Prof. Percy Quensel, of Stockholm, also dealt with metamorphic ores and illustrated the need in their interpretation of dealing with the changes in the enclosing rocks by reference to the iron ores of central Sweden. His conclusions are similar to those advocated in a review in *NATURE*, Aug. 29, 1931, p. 384, of two recent Swedish monographs on these ores. These iron ores occur in the leptite formation, which consists mainly of altered acid lavas and tuffs that have been altered into granulitic gneisses. The bedded siliceous and calcareous ores in the lower part of the formation are altered sediments. The skarn ores are due to four stages: (1) metasomatic mineralisation of limestone and

dolomite; (2) formation of the 'reaction-skarn' by thermo-metamorphism with production of simple ore minerals, and local enrichments along the axes of folds; (3) intense faulting and crushing with metasomatic formation of magnesian minerals, producing 'skol' or crush-rock, and the development of albite or quartzite in the adjacent leptite; (4) local contact alteration and renewed development of skarn-minerals by the intrusion of the younger pre-Palaeozoic granites.

Such ores are therefore due more to metasomatic processes than to magmatic segregations. Dr. A. Brammall threw doubt on the primary nature of the lode metals found in granite as the results of a searching investigation of the Dartmoor granite. It contains rare gold which has been regarded, as in other cases, as a primary constituent. Dr. Brammall proved by an elaborate series of analyses and petrographic study that the Dartmoor granite has absorbed so much of the rocks into which it was intruded that the lode metals found in it may be regarded as derived from the assimilated sediments. He also threw doubt on the current theories of rock differentiation.

The lead-zinc veins of the north-eastern Pennines played a conspicuous part in the discussion on mineral veins in 1833. Current opinion on these ores was explained by Mr. K. C. Dunham, who contrasted the alternative theories—the formation of the lodes by meteoric waters dissolving ore particles from the country rocks, and their deposition by ascending deep-seated solutions. He showed that the evidence of the vertical zonal distribution of the ore, now established through the field as a whole, of the abundant fluor-spar which indicates the derivation of the ore-bearing solution from an acid magma, and of the various rare elements, all support a deep-seated origin. The surface waters, moreover, deposit only such minerals as calcite, limonite, and oxides even in the presence of abundant pyrite. The richness of the ore in the upper parts of the veins is due to the interaction there between the deep-seated and ground waters.

Mr. G. Vibert Douglas summarised the modes of origin of the chief mines of Northern Rhodesia. The Katanga type of copper and cobalt ores in dolomite he explained by an experiment he had made at N'Changa in which a solution of copper carbonate, after filtering for ten days through powdered dolomite, lost its copper; the dolomite was stained green by malachite. He attributes this type of ore, therefore, to the introduction of sulphide solutions and their concentration and deposition as carbonates. The ores of the Roan Antelope and N'Kana he attributes to the infiltration of primary sulphides, and their concentration near intrusive granite and pegmatite, and in places by deposition far from any igneous rock. The Broken Hill zinc-lead ore-bodies are pipe-like masses in dolomite. The iron-manganese ores are akin to bog iron and manganese beds, and the metals were derived from a shale that had been intruded by granite.

Dr. G. W. Tyrrell contended that it is not possible to deny the term 'magmatic' to ore deposits which

are due to the action of late magmatic residues in which water is always the predominating constituent. These deposits have been termed 'hydrothermal' by Niggli, but this usage does not distinguish between deposits of truly magmatic origin and those due to heated waters of non-magmatic derivation. There seems to be need for a term to cover the latter, although admittedly there is often difficulty in distinguishing between the two types. Perhaps the best solution would be to use the term hydrothermal for all cases of ore deposition by heated waters, and to prefix the term 'magmatic' for those in which the magmatic origin of most or all of the water is demonstrable.

Dr. Tyrrell also dealt with ore deposition and the distribution of igneous rocks, and contended that ore provinces follow the distribution of igneous provinces as between the kratogenic and orogenic regions of the crust in any given period of tectonic and igneous activity.

The complexity of origin of ores was emphasised by Prof. R. W. Brock, of Vancouver, and he welcomed Prof. Niggli's sharp distinction between ores due to the solidification of the main mass of a magma, the products of the semi-liquid extract, and the products of the fluid extract that remain in solution through a long range of temperatures. The diversity of opinions upon particular ore

deposits, remarked by Prof. Cullis, he considered satisfactory, as it shows that each deposit is being treated individually, as is necessary since more than one process is involved in most cases. Thus the Kiruna iron ores he regards as due in part to ortho-magmatic differentiation from the local syenite-porphyry, in part to later pegmatitic injection, and in part also to vein formation. He was glad that the Kiruna ore may still be considered as in part orthomagmatic, as unquestionable examples of this mode of formation are now difficult to locate. As Prof. Cullis mentioned, the nickel-ores of Sudbury are not altogether safe examples, for Dr. Cyril Knight has assembled a large number of observations that cast great doubt on their orthomagmatic origin, and Dr. T. C. Phemister has brought to light a disquieting amount of evidence that the Sudbury sill consists not of one rock showing pronounced gravity differentiation, but of two distinct rocks. Prof. Brock remarked that we can ill afford to lose this classical illustration of this possible type of ore formation, but it may be wise to prepare ourselves for such a calamity. He considers that small ore deposits are often the more instructive as to processes of formation, and that the problems of economic geology must be solved by patient and informed study in the field, laboratory work being accessory and supplementary.

### Obituary.

DR. S. E. LANE-POOLE.

WE regret to record the death of Dr. Stanley Lane-Poole, the distinguished orientalist, which took place at his residence in Brompton Square, London, on Dec. 29, at the age of seventy-seven years. Dr. Lane-Poole, who was born in London on Dec. 18, 1854, was the son of Edward Stanley Poole, of the Science and Art Department, and a great-nephew of E. W. Lane, the translator of the "Arabian Nights", the author of "The Modern Egyptians", and the compiler of an Arabic lexicon—a connexion in which he took considerable pride and emphasised by incorporating "Lane" by a hyphen in his surname.

After being educated privately, Lane-Poole entered Corpus Christi College, Oxford, in 1874, with the declared intention of devoting himself to Oriental studies. Before he took his degree in 1877, when he obtained a third class in the honours school of modern history, he was already at work in the Coin Department of the British Museum, and in 1875 had begun the publication of the Museum catalogue of Oriental and Indian coins, which was completed in fourteen volumes in 1892. He was sent by the Government on archaeological missions to Egypt in 1883 and to Russia in 1886, and from 1895 until 1897 was employed in archaeological research in Cairo. From 1898 until 1904 he was professor of Arabic at Trinity College, Dublin, acting for part of that period as secretary to the Council of the Royal Irish Academy.

The remainder of Lane-Poole's life was devoted to literary work and research. He was the author

of a number of works, some of a highly specialised character, some of a wider appeal, and of several biographies of notabilities, such as Lord Stratford de Redcliffe, Ambassador to Constantinople; Sir Harry Parkes, Minister to China and Japan; and others whose activities had been in fields in which he was interested. Two of his works of outstanding importance in Oriental studies were "Muhammedan Dynasties" (1893), a standard work of chronological reference for scholars, and the Arabic lexicon which he edited from the material amassed by Lane and published in 1893 after a labour of sixteen years. Of a large number of scholarly works dealing with the culture, art, and history of the Moslem world, the best known are "The Art of the Saracens in Egypt" (1886) and the volume on medieval India in the "Story of the Nations" series, which reached its ninth edition.

PROF. A. W. KIRKALDY.

PROF. A. W. KIRKALDY, until recently professor of economics and commerce at University College, Nottingham, and, prior to 1919, professor of finance in the University of Birmingham, who died on Dec. 29, 1931, aged sixty-four years, was one of the few British economists of the generation of teachers, now passing away, who had actual experience of routine business management for he did not enter Wadham College, Oxford, to take up academic studies until he had served in a family business in Sunderland, in many capacities, for several years. It was only natural, therefore, that

his work as teacher and as writer should be characterised by a certain impatience with the more abstract school, and by a desire to lay the foundations of economic science more securely on a basis of real fact than on speculation concerning the actions of imaginary business men and on abandoned psychological generalisations.

Prof Kirkaldy's publications include descriptive works on the British shipping industry and on the economics of transport, in addition to certain useful elementary textbooks. He was president of Section F of the British Association at the Newcastle-on-Tyne meeting in 1926, and was editor of two important reports ("British Labour", 1914-21, and "British Finance", 1914-21) of committees of inquiry set up on that occasion. These have since been published in book form, and they constitute an authoritative and a permanent record of economic movements at a most important epoch. His knowledge of business and of business men made him exceptionally welcome on councils of merchants and industrialists.

In addition to being an appointed member of several Trade Boards, Prof Kirkaldy served on the Nottingham Chamber of Commerce, taking his turn as president of that body and acting as its delegate and as economic adviser at important meetings of the Associated Chambers of Commerce. He also acted for many years as one of the honorary auditors of the accounts of the British Association. He was a valued member of the college staff at Nottingham, and he played a prominent part in the efforts there to raise the prestige of that institution and to secure a charter conferring full

university powers. His loss is one which will be seriously felt in many varied spheres.

WE regret to announce the death of Mr Francis A Towle on Jan 10, at the age of fifty-seven years. He will be remembered by a large number of scientific workers and others through his official connexion with the Royal Society, of which he had been assistant secretary since 1921, while for the preceding twenty years he had been clerk to the Government Grant Committee. Mr Towle's earlier life was spent in Birmingham. His keen, incisive manner will be missed by many fellows of the Society that he served so zealously during a period of active expansion in many directions. Outside his work, he showed great interest and skill in all kinds of mechanism, and sometimes regretted he had not devoted himself to engineering. For example, he built model locomotives that ran on miniature railway systems of his own construction, and installed electric light plant in at least one country-house. Mr Towle was also an enthusiastic photographer, and will certainly be missed in the Camera Club.

WE regret to record the death, at the early age of forty-eight years, of Marc Bridel, of the Muséum national d'Histoire naturelle and chief pharmacist to the Hôpital Lariboisière, Paris. M Bridel, a pupil of the late Prof Bourquelot, published numerous papers on vegetable glucosides and their hydrolyses by enzymes, and was a well-known figure in French chemical and biochemical circles.

### News and Views.

Prof. J C McLennan, F R S.

THE announcement that Prof J C. McLennan, dean of the School of Graduate Studies, professor of physics, and director of the Physical Laboratory at the University of Toronto, has decided to retire and make his home in England, is a matter of international concern. His resignation means the departure from Canada of one of her most distinguished men of science. Someone has said that an institution is an elongated shadow of a man. Never was this more true than in the case of the Physical Laboratory of the University of Toronto. Its achievements are the work of many men, to whom they have brought deserved recognition. None the less, the laboratory as the entity and organisation which has made it possible is a projection of the personality of Prof McLennan, and in this sense its achievements are his achievements. He became director of the laboratory under President Loudon in 1904, and professor of physics as successor to President Loudon in 1907. At that time he was the leading spirit of the Alumni Association of the University in a movement which resulted in the obtaining of permanent support for the University from the Government of the Province of Ontario. This led to the establishment of such organisations as the Faculty Union, the Students' Union, the University Press, and the erection of

Convocation Hall and the Physical Laboratory. The interest then aroused has proved to be permanent, as shown by the generous support accorded by the Government of the Province in all plans of development and expansion in the University of recent years.

UNDER Prof. McLennan's guidance, the Physical Laboratory at Toronto has contributed numerous publications that have attracted wide attention in the scientific world. At the beginning of the present century there was Prof McLennan's work in collaboration with Prof E F Burton on penetrating radiation, better known now under the name of cosmic rays. His work with Carr on spark potentials is a classic in this field. About 1910 his attention was directed to the field of spectroscopy. This resulted in a flow of papers unravelling the mysteries of the structure of spectra of many elements and the laws connected therewith. This work was temporarily interrupted by the War, when Prof McLennan was scientific adviser to the British Admiralty. On his return, new fields of research were opened up by the liquefaction of helium at Toronto. Utilising these low-temperature facilities, researches in spectroscopy were undertaken, in which it was proved that the excitation of atomic oxygen was responsible for the radiation of the well-known green line in the spectrum of auroral displays. This has stimulated further research

on the constitution and state of the upper atmosphere. The study of the spectra of gases at low temperature enabled the first experimental proof of the existence of para- and ortho-hydrogen to be established. The Raman effect with liquid gases such as oxygen, hydrogen, and nitrogen has been investigated and the crystal structure of solidified gases examined. At the present time two promising lines of research are in progress. One has to do with the evaluation of spin moments of atomic nuclei deduced from a study of the fine structure of spectral lines. The other is a continuation of a series of investigations on the superconductivity of elements and alloys. It has been found that the superconducting critical temperature is progressively lowered when currents of increasing frequency are used. This opens up an entirely new line of attack upon the problem of superconductivity.

#### Early Knowledge of Iron in the Pacific

MR. T. A. RICKARD's communication on "The Knowledge and Use of Iron among the South Sea Islanders", read before the Royal Anthropological Institute on Jan. 12, offered what may be regarded as a highly probable explanation of the fact noted by early navigators, that while the inhabitants of some of the islands showed themselves eager to obtain iron, in other islands they were indifferent. It is recorded, for example, by Wallis, Cook, and others that in the Sandwich Islands, Tonga, and Tahiti the natives were prepared to go to any lengths to get iron, whereas in New Zealand and the New Hebrides they showed no such desire. Mr. Rickard finds the clue to the explanation of this difference in statements in Mindana, a Spanish explorer, who in 1567 saw "a chisel made into a nail" in the Marshall Islands, and of a native historian of Hawaii, who in 1867 said that the Hawaiians recognised iron on Cook's ship because they "had found iron in sticks washed up on the land". Thus iron would appear to have become known in various parts of the Pacific through having been washed up in driftwood. The effect of drift in the distribution of culture in the Pacific is a subject which stands in need of closer investigation, especially in relation to the various theories of culture-distribution in that area which have been put forward. Drift has been suggested, for example, as probably an element entering into the distribution of the coconut, and some years ago the late Sir Henry Howorth was inclined to think that the adoption of red as the royal colour in Hawaii and other parts of the Pacific might have been derived from the use of that colour by the Buddhists in China and Tibet, and carried thence to the Pacific by Chinese junks which had drifted, or been driven, out of their course.

#### Glacial Man in America.

THE Division of Anthropology and Psychology of the National Research Council of the United States of America, which, by its scheme of organised co-operation throughout the middle west, is doing much to ensure the recording and preservation of objects of archaeological interest already known or casually dis-

covered, as well as to promote research, has now directed attention to the possibility of obtaining evidence relating to the existence of glacial man in America from casual or commercial excavation, especially in centres where there is evidence of glaciation. American anthropologists have been much impressed by the frequency with which relics of prehistoric man have been unearthed in Europe in the course of commercial excavation, to which the attention of the expert has been attracted, or on which the workmen have been warned to be on the look-out for anything of an unusual character.

It is a well-known fact that the evidential value of a number of archaeological finds in America, for which a special significance in prehistory has been claimed, has been vitiated by the lack of trustworthy corroboratory geological and other data. The Division of Anthropology is accordingly attempting to arouse interest in such discoveries, and to disseminate knowledge of the data required by science in relation to any chance find which may be brought to light in the course of the extensive excavations by commercial undertakings, such, for example, as the railways, in various parts of America. A conference of the leading archaeologists of the United States and representative engineers was held at Chicago in April last for the discussion of this matter, and a report has now been issued by the Council (Reprint and Circular Series No. 100). The conference adopted a scheme of co-operative research, and a number of directions were prepared to be issued in leaflet form to bodies excavating in areas where evidence of glacial man is likely to occur.

#### Multi-Channel Television.

ONE of the difficulties met in designing a new system of television is the narrowness of the frequency band of the waves permissible when only one channel of transmission is used. At the Institution of Electrical Engineers on Jan. 6, C. O. Browne showed how this difficulty can be largely overcome by using a number of transmission channels. By using five channels, the frequency band is increased five times and the difficulties of design are greatly diminished. In addition, the velocity with which the scanning spots travel over the surface of the picture is decreased and the difficulties of good synchronisation are largely obviated. To get a moderately good picture, experience shows that the picture should consist of 15,000 picture points at least, and the picture must be scanned about  $12\frac{1}{2}$  times per second. This number was chosen because the standard frequency of the supply mains in Great Britain is 50. With small screens, satisfactory results are obtained, but when a ground glass screen measuring 24 in.  $\times$  16 in. is used there is a decrease in the brilliance of the received image. With the large received picture, the effect of flicker is pronounced and a higher scanning speed than  $12\frac{1}{2}$  pictures per second needs to be used. The author has investigated the best conditions for operating the Kerr cells used in the receiver, and discusses the effects produced by geometric, non-linear, and frequency distortion.

**Electric Power in Italy.**

THE generation and distribution of electric power in Italy began towards the close of the last century. Recently, owing to the great water power resources of the country, the industry has developed very rapidly. In a paper to the Institution of Electrical Engineers read on Dec 17, Mr A Dalla Verde described the high voltage systems of Italy. In 1894 a bill was passed compelling every property owner in Italy to allow overhead or underground electrical lines for industrial use to pass through his property. There are other regulations in connexion with the use of water power, which is the property of the State. The Alps and the Apennines provide the two great sources of water power. The average flow of water in the Alpine region is a minimum in February and a maximum in June. In the Apennine region, however, the average flow is a maximum in February. The greatest amount of power is derived from the Alps. Owing to the difference in the flow characteristics of the rivers in these two mountain ranges, the combined water power available is more constant than that of either. As in England and America, the power stations are of various types, standardisation being little considered in the early days. In the high power transmission lines the pressures employed are 60, 125, 150, and 200 kilovolts. In Italy there is a strong tendency towards discarding lightning 'arrestors' altogether and experiments are being carried out with underground cables. There are many different frequencies of supply, and this makes inter-connexion with the older systems difficult. Mr Dalla Verde stated that the ratio in Italy of the steam power to the water power production of electrical energy is less than four per cent.

**Unemployed Technical Men in the United States**

In every part of the United States, various movements are under way to alleviate distress among scientific and technical men during the present unparalleled unemployment crisis. In the New York metropolitan area, local sections of the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, and other bodies have established the Provisional Engineers Committee on Unemployment. The chemical societies have adopted similar measures. An honorary unemployment committee has been formed, the chief function of which is to compile a register of those seeking work, and to undertake a very thorough canvass of industrial firms, etc., for suitable openings. A further important step has been taken at Columbia University, where classes in the engineering department have been opened free to all accredited unemployed professional engineers, the number being limited merely by the size of the lecture halls. A certificate is necessary showing status and confirming that the holder is out of work through no fault of his own. The principal purpose is, says Dean Barker, to preserve the morale of those skilled men during a period of enforced idleness. It is of course recognised that these various schemes are only palliative in the face of immediate necessity. They do not touch the great fundamentals of the

problem. To achieve this far greater purpose it will be urgently necessary to contemplate some form of national unemployment insurance or some nationwide plan on the lines of the Swope or Rochester or like suggestion.

**Imperial Standardisation**

THE report of the joint meeting of the British Standards Institution and the Standards Association of Australia, which was held by wireless between London and Sydney on Jan 14, has been published (C C (OC) 5929 British Standards Institution, 28 Victoria Street, S W 1). Sir George Julius, chairman of the Standards Association of Australia, emphasised the importance of the present visit to Australia of Mr le Maistre, director of the British Standards Institution, with the view of helping in the great efforts now being made to extend the Empire markets of Great Britain. That standardisation is growing very quickly in Australia is made quite clear by Sir Henry Barraclough, who stated, in support, that there are more than five hundred special and technical committees dealing with various aspects of standardisation in Australia. Standardisation must be still further developed, for, as Sir William Larke stated, it is the most effective means of securing economic production, and the greatest common measure of agreement on standardisation throughout the British Empire will ensure the greatest and most rapid development of inter-Imperial trade.

**Viscosity of Liquids.**

INTEREST has recently been revived in the subject of liquid viscosity, for many years a happy hunting-ground for framers of empirical equations. The increase of gas viscosity with increasing temperature was early accounted for on theoretical grounds, but the contrasted behaviour of liquids remained long unexplained, and theoretical bases were lacking for the equations proposed to represent the decrease of liquid viscosity with increasing temperature. Recently Prof. E N da C Andrade has put forward a theory of liquid viscosity which envisages the transference of momentum between parallel-moving layers of the liquid as accomplished through the medium of temporary unions between contiguous molecules. The picture is that of "a transitory and fluctuating crystallisation". The theory leads to a remarkably simple exponential formula for the variation of viscosity with temperature, namely,

$$\eta = A \exp (bT^{-1})$$

The formula is remarkable, inasmuch as *two* constants suffice to express the march of viscosity with temperature over the range between freezing point and boiling point. Moreover, as is readily seen, the equation provides a simple explanation of Porter's well-known relation, which states that if we determine the viscosity-temperature relation for two liquids, and take a number of pairs of temperatures  $T_1$  and  $T_2$  at which the viscosities of the two liquids are equal, then the relation between the reciprocals of  $T_1$  and  $T_2$  is linear.

MR R M DEELEY has recently printed a pamphlet in which he considers briefly the problem of viscosity

and its relation to temperature. He discusses the relation between Langmuir's view that "atoms of tungsten, molybdenum, and platinum striking a clean dry surface in high vacuum are condensed as solids at the first collision" and "have a certain average 'life' on the surface", and the statement of Maxwell that "the collision between two hard spherical balls is not an accurate representation of the encounter of two molecules. A better representation will be obtained by supposing the molecules to act on one another in a more gradual manner, so that the action between them goes on for a finite time". Mr Deeley concludes that "this finite time would appear to be Langmuir's 'life' of chemical union". Mr Deeley also describes certain experiments on stress-strain relations in a bar of pitch described by him in the *Proceedings of the Royal Society* in 1908, and points out that, so long ago as 1888, in a paper on the viscosity of ice, published in the *Philosophical Magazine*, he suggested that gravity "may give rise to a slow change of form in an elastic substance, in the interior of which liquefaction and resolidification are constantly going on".

#### Vanishing Life of Australia

THE legal position regarding the preservation of the Australian fauna is put briefly in a letter received from an Australian correspondent in comment on our leading article of Sept. 12, which aroused interest in Australian newspapers. "The enactment of laws for the protection of the Australian fauna", he says, "does not come within the powers of the Commonwealth Government, except in so far as the export of skins, etc., is concerned; but the different States have all legislated to this end in a greater or less degree. Unfortunately, the laws (or their enforcement) are not strong enough to stop the traffic which goes on, particularly in skins of our fur-bearing animals. From the number of prosecutions, it is obvious that many evasions are taking place, and the penalties imposed upon those convicted, though often heavy, apparently do not act as effective deterrents". Our correspondent includes a cutting from the Melbourne *Argus* of Sept. 18, recording the conviction of a skin-buyer of unlawfully consigning 3821 skins of 'opossums' (really phalangers, to which an American Indian word has become mistakenly applied). The fine was £955 5s, and the dealer admitted five previous convictions, including fines of £234 10s in 1927 and, with two other men, of £616 in 1929. Yet the trade apparently is worth the risk, and so long as that is so, these fur-bearing creatures stand a poor chance of retaining their foothold.

#### Interference during Pairing in Birds.

IN giving advice on the breeding of turkeys in the *Poultry World* for Jan. 1 (p. 292), Mr Edmund Burr warns breeders against allowing a cock fowl (especially a game-cock) to run with breeding turkeys, as such a bird will often interfere with them when pairing. That cocks interfere with each other's pairing is well known, but it must be exceptionally mischievous birds that extend this interference to other kinds of poultry, while it is remarkable that a bird so powerful

and fierce as the turkey-cock permits it, especially as, unlike the fowl, he has his beak free during the act, not using it to grip the hen. M. G. Rogeron, however, in his very instructive book "Les Canards", records a similar case in which a garganey drake, infatuated with female mandarin ducks, interfered with pairing with impunity, although the mandarin drake is larger and very high-spirited, being well able to hold its own with mallard. Interference with pairing by their fellows may be the reason why the act is observable with comparatively few birds; it is not practised by the rook, but is a perfect *mama* with the house-crow of India—so much so that in eight years' bird-watching there, the writer of this note never saw the act successfully performed by that species.

#### A Prismatic Derivator.

FOR many purposes, both in physics and engineering, the derivative of a graphical record has to be taken with all the accuracy that the record allows. For this purpose, either a numerical method of differencing is usually resorted to, or a mechanical process of laying a tangent. Perhaps the best known of this latter type is that which depends on the principle that a curve and its reflection in a plane mirror pass continuously into one another when the reflecting surface lies along the normal. A prismatic derivator has been designed by v. Harbou and has been produced by Askania-Werke A.G., Bambergwerk, Berlin-Friedenau, which avoids the difficulty usually experienced of recognising when a curve and its reflection are continuous. In this new instrument a right-angled prism is placed with its hypotenuse on the paper and with the intersection of the opposite edge approximately along the normal to the curve. The portions of the curve on each side of the point at which the tangent is required, as seen after refraction through the prism faces, will not join up at the prism edge unless that edge is accurately along the normal. From the published description of the instrument, it appears that there is a number of other adjuncts that tend to increase the accuracy and effectiveness of the apparatus.

#### Photographic Research.

"ABRIDGED Scientific Publications" from the Kodak Research Laboratories, vol. 14 (1930), issued by the Eastman Kodak Co., Rochester, New York, contains, in *précis* form, a number of papers previously published in various journals. An introductory note states that the Eastman Kodak Co. does not restrict publication to a privately issued journal but desires that the results of its scientific research may be easily accessible to all interested in special branches of science. The papers cover a wide range of subjects, including physics (for example, a study in condensation pumps, and a polarising apparatus for determining extinction angles), physical chemistry (for example, the lattice energies of silver halides, the electrolytic oxidation of some photographic developers), organic chemistry (for example, the preparation of *s*-diphenylcarbazide, a colour reaction for naphthol yellow), and colloid chemistry and photographic

technique. The volume brings together a large amount of research work of high standard, the results of which will be of value in many fields. Even biology is represented in a description of the production of a motion picture showing the movements of the vocal cords in the larynx.

#### Announcements.

THE twelfth International Congress of Zoology will be held at Lisbon in the summer of 1935, under the presidency of Prof. Arthur R. Jorge, professor of zoology in the University of Lisbon.

THE Duddell Medal for the year 1931 has been awarded by the council of the Physical Society to Prof. C. T. R. Wilson, Jacksonian professor of natural philosophy in the University of Cambridge.

PROF. ARTHUR HOLMES, professor of geology in the University of Durham, sails from England on Feb. 20 to deliver a course of eight lectures on "Radioactivity and Geology" at the Lowell Institute of Boston, Mass. The lectures begin on March 4. Prof. Holmes will also give a lecture on "The Age of the Earth", before the Royal Canadian Institute at Toronto, on April 2.

IT is announced by Science Service, of Washington, D.C., that Dr. John J. Abel, professor of pharmacology in the Johns Hopkins Medical School, Baltimore, Md., was elected president of the American Association for the Advancement of Science meeting at New Orleans, in succession to Dr. Franz Boas, the distinguished anthropologist of Columbia University. Dr. Abel was the first to obtain in chemically pure state the secretion of the suprarenal glands, to which he gave the name epinephrine, also known as adrenalin. He was also successful in isolating the active principles of the pituitary gland and was the first to obtain insulin in crystalline form. The prize of 1000 dollars offered for a paper read at the annual meeting of the American Association has been awarded to Dr. C. C. Speidel, of the University of Virginia, for a paper on the development of nervous tissue.

THE Council of the Geological Society has this year made the following awards: Wollaston Medal to Prof. J. H. L. Vogt, of Trondhjem, Norway, in recognition of the value of his researches concerning the mineral structure of the earth, and especially his pioneer work in the application of physical chemistry to the origin of igneous rocks and ore-deposits; Murchison Medal, together with the sum of ten guineas from the Murchison Geological Fund, to Prof. William G. Fearnside, in recognition of the value of his researches in the Lower Palaeozoic rocks of Wales and other geological investigations; a Lyell Medal, together with the sum of £30 from the Lyell Geological Fund, to Mr. Henry Dewey, in recognition of the value of his researches in the geology of the south-eastern parts of England, more especially the Quaternary deposits of the London Basin; another Lyell Medal, together with a like sum of £30 from the Lyell Geological Fund, to Dr. M. M. Ogilvie Gordon, in recognition of the value of her researches on the

structure of the Western Dolomites (Tirol); the balance of the proceeds of the Wollaston Donation Fund to Dr. Ernest Neaverson, in recognition of the value of his researches in the structure and geological history of the Cephalopoda; the balance of the proceeds of the Murchison Geological Fund to Dr. A. K. Wells, for his contributions to petrology, and more particularly for his researches on the Ordovician igneous rocks of parts of Wales and the plutonic rocks of the Channel Islands; the balance of the proceeds of the Lyell Geological Fund to Mr. R. W. Pocock, in recognition of the value of his geological work on the older rocks of the Welsh borderland.

MESSRS. Longmans and Co., Ltd., announce for early publication "The Causes of Evolution", Prof. J. B. S. Haldane; "Sulphur Bacteria", Prof. D. Ellis; "Vision and Colour Vision", Dr. R. A. Houstoun; and "Modern Practice in Mining", Sir Richard Redmayne—Vol. 5: "Colliery Machinery and its Application".

PROF. F. SODDY is publishing through John Murray a new work entitled "The Interpretation of the Atom", which will take the place of the same author's "Interpretation of Radium". It will be in two parts, dealing respectively with the radioactive elements and isotopes, and the general progress of atomic chemistry.

WE have received a copy of a prospectus describing a facsimile edition of the most ancient manuscripts and maps of Ptolemy. The work, which is to be published in an edition of 350 copies by E. J. Brill, of Leyden, and O. Harrassowitz, of Leipzig, is edited by Dr. J. Fischer, who discovered in the Codex Urbinae Graecus 82 of the Vatican Library the oldest Greek maps and text of Ptolemy. These twenty-seven maps, which hitherto have not been published, are now reproduced full size. The work will also contain, in addition to the Greek text in full, twenty-seven maps of the oldest Latin manuscript, a large number of maps from various Greek and Latin manuscripts of Ptolemy giving all the known types, a monograph on the life and works of Ptolemy by Dr. Fischer, and a critical introduction to the Greek text. There will be four volumes, including one of folio size.

MESSRS. W. JUNK, of Berlin, publishers and dealers in second-hand books and pamphlets, have issued a sumptuous catalogue of their publications and stock. Zoologists need not to be reminded of the invaluable monographs which Messrs. Junk have made available for reference—the series of "Catalogi Coleopterorum, Lepidopterorum, Fossilium", and the six-volume "Tabulae Biologicae", which stands by itself as a work for consultation in its particular sphere. Almost exactly half the present book catalogue of 290 pages deals with the natural history publications of the firm, and the other half contains a list of second-hand books and pamphlets. The extent of the second-hand collection may be gauged by the fact that a single page is devoted to the briefest summary of a series of 75,000 papers on zoology, botany, palaeontology, geology, and mineralogy, which is priced at £1275.

### Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

#### *Ovis astore*, a Three-Coated Sheep.

ABOUT 1912 the many interesting experiments in sheep-breeding carried out at Colesbourne by the late H. J. Elwes directed the attention of both sheep breeders and wool users to the many types of sheep, wild and domesticated. It was left to Prof. Cossar

FIG. 1.

Ewart, of the University of Edinburgh, to evolve from the primitive characters and types a key scheme explanatory of the origin of the present-day breeds of domestic sheep. This he did by referring all breeds back to two fundamental types, namely, the Urial-Mouflon, which still has representatives in Asia, Europe, and America, and the fat-tail-fat-rump, based on the *Ovis ammon*, which seems to be a special development to meet the changed environment follow-

FIG. 2.

ing the drying up of the Gobi Sea. Many evidences of these two types of sheep are to be noted in carefully selected present-day flocks (see NATURE, May 6, p. 595; 1922).

Turning from an examination of the body contour

No. 3247, Vol. 129]

of the various domestic sheep, Prof. Ewart next considered the woolly coat and at once made the discovery that the wild sheep is usually double-coated, carrying an outer coat of long, coarse fibre and an under coat of very fine fibre, and that the coats of many of the domestic breeds can be explained by postulating the casting of the outer coat of hair and the development of the under coat of wool. In 1923, during the meeting of the Pan-Pacific Congress in Sydney, attention was first directed to the fact that even our finest woolled sheep, the merino, usually carries a double-coat at birth, but that within a few weeks it casts the hair-coat, possibly as kemps, and becomes single-coated.

Since these facts and suggestions were put forth, endeavours have constantly been made to refer back every class of fleece to the double-coated type; but from time to time difficulties have been encountered, scarcely consciously realised, in doing this.

While in Srinagar (Kashmir) last July, a sheep was brought from Astore (Gilgit) for my inspection (Figs. 1 and 2) which seems to throw a flood of light upon the difficulties from time to time encountered, and may result in a more perfect explanation of the varying coats of our domestic sheep than has been

FIG. 3.

offered by attempting to refer every type back to the two-coated sheep (Fig. 3). The general appearance of the *Ovis astore* is black with bleached fibre tips, but I was surprised, on examining a staple of wool, to find that this appearance is due to a long, strong white fibre thrusting itself through an under coat of strong brown or black fibre, and that in addition to these two coats is a third coat of fine white wool. Careful measurements of these three types of fibres have been made, with the following result:

| Fibre Type.       | Minimum Diameter (in.). | Maximum Diameter (in.). | Average Diameter (in.). | Approx. per cent.* |
|-------------------|-------------------------|-------------------------|-------------------------|--------------------|
| White outer coat  | 1/582                   | 1/339                   | 1/447                   | 12                 |
| Black under coat  | 1/700                   | 1/223                   | 1/397                   | 17                 |
| White middle coat | 1/1170                  | 1/552                   | 1/742                   | 71                 |

\* This appears to vary according to the position selected on the sheep.

If a hundred measurements of each type of fibre are made and the results plotted as a diameter frequency distribution curve, the result shown in Fig. 4 is obtained.

The curves for each type of fibre show that the white outer coat and the white middle coat fibres come on to much shorter bases than the base of the black under coat fibres and are almost equally distributed on either side of the mode, as against the

black fibres, which, extending in an extraordinary manner towards the coarse end of the scale, are anything but balanced. The three scales overlap, but the fibres seem sufficiently distinct in appearance to warrant them being put into these three distinct classes.

As these sheep are sheared twice a year, it has not been possible to ascertain how the coats are shed. This particular sheep, however, is kindly being kept under observation by Mr C R Kohh, Director of Industries for the Kashmir State, and within twelve months definite details of the shedding or non-shedding of the coats will be available. It will be noted that the head of the sheep is of the *Ovis polii* type, and an endeavour is being made to link the three coats up with the *Ovis polii* type of sheep, as distinct from the *Ovis ammon*.

This discovery leads to many important questions, of which perhaps the most important is: Can the types of fibres produced by the sheep be linked up in any way with the skin structure? The opinions of

to the present, we are really in a dilemma, although most authorities have accepted the first explanation. *Ovis astore*, however, seems likely to solve this dilemma.

#### Death of Fish in the Tees Estuary.

For several years past, migratory fish passing through the Tees estuary have been killed in large numbers. This is most noticeable in the months of April, May, and June, during the seaward migration of young salmon (*Salmo salar* L.) and sea trout (*Salmo trutta* L.), when many thousands are found dead on the foreshore. An extensive biological, chemical, and hydrographical survey of the river, undertaken by the Department of Scientific and Industrial Research as part of the programme of the Water Pollution Research Board, has provided an opportunity for an investigation into the cause of this mortality.

The estuary is polluted by the untreated sewage from a population of about 275,000, and by large volumes of industrial wastes, produced mainly in the processes associated with the iron and steel industries, and consisting chiefly of coke oven effluents and spent pickle liquors from galvanising plants. As a result of this pollution, the waters of the estuary are partially deoxygenated, the deficiency increasing with increasing water temperature, and reaching values as low as ten per cent of saturation at maximum summer temperature. During the months April, May, and June, however, when the smolts are killed, the dissolved oxygen deficiency is usually insufficient to account for the mortality. An examination of the directly toxic effluents entering the estuary was, therefore, undertaken.

Spent pickle liquors contain about forty per cent of ferrous

chloride in acid solution, and in the alkaline waters into which they are discharged the iron is almost immediately precipitated. In the concentrations in which they occur, these effluents have no appreciable effect on the toxicity of the estuary.

Coke oven effluents, on Tees-side, are of two kinds, resulting from the semi-direct and direct processes of ammonia recovery. By a series of experiments, in which the various groups of substances found, by analysis, to be present were each in turn eliminated, the toxicity of the semi-direct process effluents was shown to be due mainly to phenolic bodies, and that of the direct process effluents to cyanides.

The concentrations of both tar acids and cyanides normally present in the estuary are of the order to be expected from the volumes of effluents discharged and the volume of estuary water available for their dilution. The concentration of tar acids present, except in very restricted areas, is never sufficiently high to be toxic to fish, but cyanide is frequently found in lethal concentrations in the general body of the estuary water.

During the smolt migration of 1931, water samples from the mortality zone of the estuary were collected every day, their dissolved oxygen and cyanide contents were determined, and their toxicity to trout was measured by experiment. The oxygen concentrations ranged from forty to seventy per cent of saturation (water temperature 10°-14° C), and were too high

FIG 4

physiologists on this matter would be very valuable. If a small staple of fibres is pulled from a merino sheep, it has been observed that it brings with it the complete embedding skin. The wool of the normal British sheep seems more deeply embedded in the skin, and, so far as I am aware, a staple pulled away never brings the skin with it. This suggests that fine wool fibres grow shallower in the skin than the coarser wool fibres or hairs.

There is, however, an even more interesting problem involved. The blackface breed of sheep appears to grow the double coat, an outer coat of strong fibre and an under coat of fine fibre. The under fine coat is shed each year, usually in the late spring, whereas the outer coat is never shed, or at least never shed as one complete coat. Now, the coat of the merino sheep is supposed to be based upon the elimination of the outer coat of hair and the development of the under coat of wool. But, as we have already noted, the merino sheep, as a lamb, sheds its outer coat of hair but will retain its under coat of wool for five or more years without evidence of any break along the fibre length. Hence the question arises: Is the coat of the merino based upon the under coat of the wild sheep with a suppression of the shedding factor? Or is the coat of the merino sheep, after all, a modification—a most marked modification—of the outer coat of the wild sheep, the under coat being eliminated? Up

to account for the observed mortality. It was found that the toxicity increased with increasing cyanide concentration. In 130 out of 138 toxic samples the toxicity was completely removed by the addition of a small quantity of formaldehyde, which removed the cyanide present by forming with it innocuous compounds, but did not alter the tar acid or dissolved oxygen concentrations. The colour of the gills of smolts dying at the surface of the estuary waters was found to be markedly brighter than that of normal fish. It was shown experimentally that, of the poisons likely to be present in the estuary, cyanide alone produced this effect.

The evidence therefore points to the conclusion that cyanide is the factor mainly responsible for the death of fish in the Tees estuary. The importance of cyanides in the study of pollution has been noted by Lehmann,<sup>1</sup> but his work has attracted little attention in Great Britain.

A method whereby cyanide-containing effluents from coke ovens are rendered innocuous by the addition of spent pickle liquors is being worked out, and it is hoped that treatment on a works scale will soon be possible.

#### A New Series of Allelomorphs in Mice.

THERE appeared recently<sup>1</sup> a paper by P. J. Cammidge and H. A. H. Howard on "The Hereditary Transmission of Hypoglycæmia in Mice" which contains facts of considerable interest to students of genetics. These authors had previously shown that the condition of high blood sugar in mice (hyperglycæmia with blood sugar values of 110-125 mgm per 100 c.c. of blood) behaves as a simple recessive to the normal condition (about 80 mgm).<sup>2</sup> They have now found mice with very low blood sugar value (about 60 mgm), and this condition also behaves as a simple recessive to the normal. Segregation in both cases is clear, no intermediate values having been found.

The experimental evidence, allowing for a lower viability of hypoglycæmic animals, seems sufficient to justify the authors' conclusions that they have discovered another recessive gene influencing the blood sugar level of the blood. They seem, however, not to have noticed the important fact that the three blood sugar levels—high, low, and normal—appear from their evidence to be due to three allelomorphic conditions of the same gene. A summary of the crosses which show this follows.

High  $\times$  normal  $F_1$ , normal,  $F_2$ ,  $\frac{3}{4}$  normal,  $\frac{1}{4}$  high (actually 81/28)

Backcross,  $F_1 \times$  high,  $\frac{1}{2}$  normal,  $\frac{1}{2}$  high (actually 45/44)

Low  $\times$  normal;  $F_1$ , normal,  $F_2$ ,  $\frac{3}{4}$  normal,  $\frac{1}{4}$  low (actually 45/10 + 5 dead)

Backcross,  $F_1 \times$  low,  $\frac{1}{2}$  normal,  $\frac{1}{2}$  low (actually 77/26 + 40 dead)

Low  $\times$  high,  $F_1$ , high,  $F_2$ ,  $\frac{3}{4}$  high,  $\frac{1}{4}$  low (actually 46 high, 10 low + 6 dead)

If the mice born dead are assumed to be hypoglycæmic, the results fit the expectations remarkably well. But the results of crossing low by high show that these conditions are not only allelomorphic with normal, but also are probably allelomorphic with each other as well. Normal, high, and low appear to form

a series of triple allelomorphs with dominance in the order given. This dominance order is unusual, if not unique, among multiple allelomorphic systems, since a high quantitative effect on blood sugar appears between two lower values. Further evidence from crosses of high by low and of each by the same normal stocks would seem desirable to test the possible influence of modifying genes in producing this unusual result.

L. C. DUNN

Columbia University,  
New York City

<sup>1</sup> *Proc. Roy. Soc. Med.*, vol. 23, 1930

<sup>2</sup> *J. Genetics*, vol. 16, 1926

THE case to which Prof. Dunn alludes is of very great interest in the question of the origin of dominance. It will be observed that the gene for normal blood sugar is dominant both to the hyperglycæmic and to the hypoglycæmic genes. In the "Genetical Theory of Natural Selection" (Chap. v), I had inferred that such dominance in opposite directions to different mutants must occur in quantitative characters, if dominance is, as I believe, a product of natural selection. With respect to the exceptional dominance of the one mutant gene over the other, it will be observed that this also follows the rule of the dominance of the more over the less viable condition. It is much to be hoped that further evidence of this observation will be obtained, using genetically normal, wild type mice, since the fact that in this cross an intermediate heterozygote would seem to be more advantageous than one with high blood sugar, suggests that the case may throw light on the mechanism by which the recessiveness of hypoglycæmia has been brought about.

#### A Fertile Mule.

ON Nov. 24, 1924, a common mule on the farm of Mr. W. J. Kilian, of Weenen, Natal, gave birth to a male foal, and a detailed account of the occurrence was given in the *Annals of the Natal Museum*, vol. 5, pt. 5, 1926. The mule in question was bred by Mr. W. L. Eales, of Fullerton, Cape Province. It is a typical mule in every way, and has a considerable preponderance of the characters of the ass.

The foal was suckled by the mother mule. The foal grew rapidly and the adult animal is now a reliable riding horse, and from the accounts received it is practically indistinguishable from a pure horse.

The subject has again been brought to my notice, in that on Nov. 21 of this year the same mule, which is about fifteen years old, gave birth to a second male foal, and this foal was sired by a different stallion from that of the first foal. Thus, between the births of the two foals there has been an interval of seven years, although the mule has been repeatedly served. In the present foal the characters of the horse would appear to be markedly prepotent over those of the mule, just as in the case of the first foal.

It would seem as though South Africa were in some way favourable for mule-fertility, in that in 1904 the late Dr. Gunning, director of the Transvaal Museum, informed me that he was acquainted with an undoubted case in the Transvaal, but, so far as I am aware, the exact details were never published.

That the common mule may be sometimes fertile has been long disputed, although certain alleged cases have been quoted from America, but they mostly seem to lack strict authenticity. Also, on cytological grounds even the possibility of back-crossing

has been questioned, owing to the fact that a highly confused chromosome complex has been found in the mule

There is here, however, an indisputable case of mule-fertility, and the theoretical assumptions are thereby shown to be invalid

### Vocal Powers of Kangaroos.

IN the notes on Sir Peter Chalmers Mitchell's address to the British Association on "Zoos and National Parks",<sup>1</sup> the statement is made that the "kangaroo is never known to utter any kind of sound normally", etc. This is misleading, as, under entirely 'normal' conditions, kangaroos of several species, both 'in the wild' and in captivity, frequently make two distinct sounds and occasionally a third

(1) A soft, frequently repeated, 'chittering' sound, made without perceptible movement of the lips and possibly produced by expulsion of air through the nostrils. In pet kangaroos it is frequently produced when the animal responds good-humouredly to gentle teasing, but amongst the gregarious small wallabies (*Thylogale*) a very similar sound is used by females to recall young to the pouch

(2) A loud, discordant, aspirate sound, which may be roughly imitated by the long-drawn-out enunciation of the word 'harsh'. Chiefly indicative of anger and of pain, it is almost always heard when a wounded male is approached, and is sometimes used also by the rutting bucks, in the concluding phases of their pursuit of the females

(3) A distinct, short, clear-cut bark or cough, made as a warning signal by a member of a 'mob', when suddenly disturbed. Although mentioned more than once in the older literature on Australian natural history, it is not given much credence here, but I can vouch for its reality from personal experience, having heard it on two occasions, in Gippsland and southern New South Wales, when observing parties of *Macropus giganteus typicus* at close quarters in heavy timber, and once (by *M. giganteus fuliginosus*) in the Zoological Gardens at Adelaide

### St Kilda House Mouse.

THE St Kilda house mouse (*Mus musculus muralis*, Barrett-Hamilton) received great notoriety when the island was evacuated in 1930, because it was confidently expected to become extinct. Some previous writers (Ritchie, *Scot Nat*, 1930) stated that the mouse was confined to the Post Office buildings on the island. A visit to St Kilda this summer proved to us that the mouse has become extremely rare and at present only inhabits two houses in which food was left behind. It is particularly interesting to note that neither of these houses is the Post Office, and the evidence of the inhabitants, and of previous visitors, confirms the view that the mouse was never confined to one building.

Waterston (*Ann Scot Nat Hist*, 1905) described a number of house mice from Lochmaddy, N. Uist, which in every way resembled the light-bellied *Mus musculus muralis*, and were found living with the normal *Mus musculus*, but apparently without hybrids. This discovery seems to have been overlooked by sub-

sequent investigators, and points to the mouse not having such a confined geographical distribution as is generally credited to it

### Cytology of Mycetozoa

IN her paper entitled "The Life-History and Cytology of *Didymium nigrupes* Fr",<sup>1</sup> Dr E. J. Cadman has made a valuable contribution to the literature on Mycetozoa. The principal points described by her are the following: the active swarm-cells possess what she terms a "centroblepharoplast" and cone apparatus connecting the flagellum with the nucleus; the nucleus of the swarm-spores has four chromosomes; a definite myxamœboid stage occurs when all trace of cone-apparatus disappears; the myxamœbæ unite in pairs as gametes to form a zygote or young plasmodium, and their nuclei also fuse; the fusion nucleus contains eight chromosomes; a diploid number characteristic of all succeeding nuclei of the plasmodium; meiosis occurs in the nuclei of the young sporangium before spore-formation, when a heterotypic division with four U-shaped chromosomes is swiftly followed by a homotypic division with four nearly spherical chromosomes.

Schunemann,<sup>2</sup> working with the typical form of *D. nigrupes*—Dr Cadman deals entirely with var. *xanthopus* of that species—also observed the union of myxamœbæ to form gametes, but he did not see fusion of their nuclei; he also describes meiosis in the nuclei of the young sporangium before spore-formation. He found the number of chromosomes in the nuclei of the swarm-cells and plasmodium to be eight and sixteen respectively. It is interesting that the var. *xanthopus*, a variety apparently closely allied to the typical form, should be found by Dr Cadman to possess only half the number of chromosomes in those two stages.

By way of criticism, several points may be noted. Dr Cadman says (p. 106) that "the spore-membrane consists of a single membrane, not a double one as stated in Lister's Monograph". The statement is undoubtedly too general and should have been qualified; double spore-walls occur, however, in several species of the genus *Didymium*, in *Mucilago*, and in species of *Trichia*, as observed by De Bary<sup>3</sup> and others. Dr Cadman disregards the numerous completely satisfactory monospore cultures carried out by Jahn<sup>4</sup> in *Didymium squamulosum* Fr., and by Miss Cayley<sup>5</sup> and also by Schunemann in *D. nigrupes* and *D. difforme* Duby, when all stages in the life-history, the germination of the spore, the increase of swarm-cells, and the formation of healthy plasmodia and sporangia were followed. Dr Cadman seems scarcely to give due weight to the observations of Miss Cayley and Miss Waterhouse, who succeeded in watching in thirteen instances the gradual fusion of flagellate gametes in living monospore and plurispore cultures of *D. difforme*. She is not quite correct in stating that Miss Cayley considers that sex-segregation is closely connected with meiosis, for, although Miss Cayley's diagram illustrating the stage at which sex-segregation might occur is rather misleading, she writes (l.c. 245), "there is no experimental proof that the first division of the emerging swarm-spore is the critical one as far as sex is concerned", and indeed her view is that, although the evidence is not conclusive, her observations, and Jahn's, tend to show

that sex-segregation does not take place at meiosis Dr Cadman herself is of the opinion that in the two species of Mycetozoa she has investigated, *D. nigripes* var. *xanthopus* and *Reticularia Lycoperdon* (Bull.), "there is no difference, morphological or physiological, between the gametes in either species."

In conclusion, it may be said that anyone who has worked at the cytology of this group will appreciate the technical difficulties that are involved in its investigation.

### Carbon/Nitrogen Ratios in Cacao Soils.

By tabulating and comparing the results of a detailed laboratory examination of profile samples of cacao soils collected in January 1930, in the island of Tobago, British West Indies, one of us (G. G.) was able to demonstrate<sup>1</sup> a close correlation between the yielding capacity and the carbon/nitrogen ratio for the organic matter contained in the surface six-inch layer of soil. The mean ratio for 'good' soils yielding more than 8 bags (or 1320 lb.) of fermented and dried cacao beans per 1000 trees (pickets) is 8.3 (21 samples), and for 'bad' soils yielding less than 8 bags per 1000, 6.8 (10 samples). Statistically, this correlation is highly significant ( $t=4.5$ ), and the C/N ratio is not necessarily dependent on the total amount of organic matter present ( $t=1.1$ ). Although a complete explanation of this relationship is not yet forthcoming, the result implies that the nature of the organic matter present, rather than its total amount, is the primary factor concerned in the productivity of cacao soils under the climatic, cultural, and soil conditions that obtain in Tobago.

Afterwards, similar comparisons of yields and C/N ratios for cacao soil—profile samples collected in Trinidad and in Grenada, B. W. I.—have been established. The following additional results have been demonstrated.

|                          | Mean C/N Ratios (Top 6 in Soil)                         |                                                        |
|--------------------------|---------------------------------------------------------|--------------------------------------------------------|
|                          | 'Good' Cacao Soils<br>(Yield, more than<br>8 Bags/1000) | 'Bad' Cacao Soils<br>(Yield, less than<br>8 Bags/1000) |
| Trinidad                 | 7.0 (54 samples)                                        | 5.7 (46 samples)                                       |
| Grenada                  | 8.0 (23 samples)                                        | 6.5 (12 samples)                                       |
| (Tobago, for comparison) | 8.3 (21 samples)                                        | 6.8 (10 samples)                                       |

Whilst these results substantiate the earlier Tobago result, the numerical values of the C/N ratios for the Trinidad and the Grenada soils are not identical with those for the Tobago soils, but they are of the same order of magnitude, and their differences are approximately the same.

A comparison of the climatic, cultural, and soil conditions within the three areas is instructive. The climatic differences are not very marked. Within each area, the annual rainfall (45 to 120 inches) is distributed between seven wet months (June to December) and five dry months. The cultural treatment is somewhat similar, except that leguminous shade trees (*Immortel*) are generally grown in the cacao fields of Trinidad and Tobago, but not in those of Grenada, whilst artificial manures are regularly employed in Grenada but not in the other islands. The soil types

are markedly different. The cacao soils of Trinidad are mainly derived from Tertiary sedimentary rocks and from their recent alluvial representatives, but some alluvial soils of the Northern Range of mountains are derived from Palaeozoic dynamo-metamorphosed sediments. The cacao soils of Tobago are about equally distributed between—(a) metamorphic sedimentary rock types, similar to those of northern Trinidad, (b) partly metamorphosed, intrusive basic igneous rock (epidiorite) types, and (c) alluvial equivalents of both. The cacao soils of Grenada are derived from Pleistocene basic volcanic rocks (hornblende and augite andesites and olivine basalts, lavas, intrusions, and fragmental rocks) or their alluvial derivatives. Detailed studies of all these soil types are now being prosecuted at the College, and include a special investigation of the transformations of their organic matter contents. It is hoped thereby to discover the true significance of the C/N ratio of soil organic matter in its relation to nutrition of the cacao tree.

### Raman Lines and Infra-Red Bands in Nitrous Oxide.

THE question whether or not the  $N_2O$  molecule is linear, and if so, whether the oxygen atom occupies a position between the two nitrogen atoms or at one end, was discussed by Snow<sup>1</sup> some time ago. The incomplete evidence then available seemed to favour the symmetrical configuration. We have, however, been able to show conclusively that the molecule is unsymmetrical, though linear.<sup>2</sup> The form of the bands and the spacing of the rotation lines is inconsistent with any but the linear model. The selection rules for vibrational transitions and for the appearance of zero branches, and the fact that all three fundamental frequencies are optically active, indicate the asymmetry.

The lowest frequency fundamental vibration, designated as  $\nu_2$ , involves simultaneous displacements of the three atoms perpendicular to the linear axis, the central atom moving toward one side and the extreme atoms toward the other. Dennison<sup>3</sup> has shown that in the first excited state each atom executes a circle about its normal position as centre. The molecule thus becomes a very slender rotating triangle the lengths of the sides of which *do not vary*. Consequently there is no change in polarisability with phase, and, according to Placzek,<sup>4</sup> no Raman scattering. A second fundamental frequency, designated as  $\nu_1$ , involves simultaneous displacements of the two extreme atoms towards and away from the centre, with rapid changes in polarisability, and should give an intense Raman line. We find this band in the infra-red at  $1285\text{ cm}^{-1}$ .

The third fundamental frequency,  $\nu_3$ , which we find at  $2224\text{ cm}^{-1}$ , involves displacements of both extreme atoms in one direction along the axis and of the central atom in the opposite direction. If the molecule were symmetrical (both extreme atoms identical) the configurations at phases one-fourth and three-fourths would be mirror images of one another. At zero phase the polarisability would be either a maximum or a minimum, the sequence of values assumed during half of the period being repeated precisely during the next half period. Thus no Raman displacements of the fundamental frequency would occur. For the

unsymmetrical molecule, however, this would not be the case, and Raman lines would be expected, though perhaps with low intensity

The observations of Bhagavantam<sup>5</sup> corroborate in a satisfactory manner our conclusions regarding asymmetry. He finds an intense Raman line with the displacement  $1283\text{ cm}^{-1}$ , and a rather weak line with the displacement  $2226\text{ cm}^{-1}$ , in very good agreement with our values for  $\nu_1$  and  $\nu_3$ . The former corresponds to the intense scattering in  $\text{CO}_2$  associated with the symmetrical and optically inactive vibration at about  $1338\text{ cm}^{-1}$ , but for the latter  $\text{CO}_2$  has no counterpart, in spite of the fact that its strongest infra-red absorption band occurs at  $2349\text{ cm}^{-1}$ .

Because of the small energy and double weight of the first vibration state  $\nu_2$ , a large fraction of the  $\text{N}_2\text{O}$  molecules (about one-eighth) are excited to this level at room temperature. The Raman displacements for light scattered by these excited molecules would be slightly different from those for normal atoms, giving rise to satellite lines. From combination relations we are able to predicate the positions of these weaker lines, not yet observed, their displacements should be  $1278\text{ cm}^{-1}$  and  $2210\text{ cm}^{-1}$ . Lines corresponding to the stronger of these have already been observed in the Raman spectra of  $\text{CO}_2$  and  $\text{HCN}$  precisely at the positions indicated by the infra-red observations.

### Selective Action of Living Tissue to Homogeneous Radiation

A SELECTIVE action has been observed<sup>1</sup> when the allantoic membrane of the embryo chick is exposed to homogeneous X-radiation obtained by crystal diffraction.

The biological response, depicted in Fig 1, A, may be described in terms of a series of maxima connected by an empirical formula  $\lambda = kn^2$ , where  $\lambda$  is expressed in cm,  $k$  is a constant equal to  $3.2 \times 10^{-10}$ ,

FIG 1

and  $n$  is given successive integral values from 2 to 8 (Fig 1, B)

A 'maximum' is predicted at a wave-length of  $3.2 \times 10^{-10}\text{ cm}$  by making  $n$  equal to 1, but unfortunately the experimental investigation would be very difficult.

The position of a 'biological maximum' is only known within a margin of  $\pm 0.25 \times 10^{-9}\text{ cm}$ , owing to the use of comparatively wide spectrometer slits, and the experimental evidence is somewhat scanty for high and low values of  $n$ . Nevertheless, there are great difficulties in associating the selective action with the K and L levels of heavy atoms, some of which are present in minute quantities (Fig 1, C) (Tungsten, silver, and bromine are not present, but of importance in energy measurement).

The suggestion is made that the above formula might be associated with a series of nuclear energy levels in one of the light atoms which form the main bulk of living tissues.

### Effect of Light on the Surface Tension of Boys's Soap Solution

IN his letter in *NATURE*,<sup>1</sup> Dr P. Lecomte du Nouy says "As the concentration of the soap solution + glycerin which he [L. D. Mahajan<sup>2</sup>] uses is not stated, but may be as high as 2.5 per cent—which should give a very small drop—it is indeed quite possible that illumination plays a part in this case."

Dr du Nouy and others who are interested in the subject may be interested to know that I used Boys's soap solution and its various dilutions—even up to one per cent of the Boys's soap solution in the dilution. The minimum strength of the sodium oleate in the dilution which I studied was  $2.5 \times 10^{-4}$ . In all observations the results obtained were found constant throughout for all dilutions. The details of the above work<sup>3</sup> are published in the *Indian Journal of Physics*.

I am now trying still higher dilutions, even up to  $10^{-8}$ . The results are appearing hopeful again, and interesting, and will shortly be published.

### An Agricultural Pamphlet.

IN 1905, Wilfarth, Romer, and Wimmer published in the *Landw. Versuchs. Stat.*, vol 63, a paper, "Über die Nährstoffaufnahme der Pflanzen in verschiedenen Zeiten ihres Wachstums." The importance of this paper in agricultural science was soon recognised, and before long an English translation was published in pamphlet form. Copies of this were obtained by the libraries at Rothamsted and at the Ministry of Agriculture, but not apparently by the British Museum or the Science Library.

The Rothamsted copy was obtained in the days when our library was not properly constituted, we had only very few books and no librarian, and we did not take the full bibliographical details. Our copy has long been missing, and on inquiry at the library of the Ministry of Agriculture we find that by a strange coincidence theirs also cannot be found, so that we know neither the translator nor the publisher, and consequently cannot take steps to obtain a new copy.

I should be grateful for bibliographical information, or, better still, to learn where I can now obtain another copy.

## Research Items.

**Eyebrows and Eyelashes in Man**—A preliminary report on a study of the eyebrows and eyelashes in man, a subject not hitherto treated in anthropological literature, is published by Prof V Suk and Dr F Rozprým in *Pub* No 142 of the Faculty of Science of the Masaryk University, Brno. The study deals specifically with form and colour and the question of heredity. Eyebrows are divided into 11 types according to form, which varies extensively. Of 470 cases the greatest number are classified as 'spreading', those which are evenly formed on each side occurring much more rarely, 96 cases of the latter as against 157 of the former. The 'even' occurs 20 times as frequently in women. 'Peaked', rising in the middle, is rare, occurring 12 times only. 'Narrowing', in which the eyebrows are thick at the medial end and narrow towards the distal side, seems to be a feminine form, occurring three times as often in women. A whorl running outward from the nose is also feminine. There is no correlation between form and colour. In the eyelashes the upper are more characteristic than the lower. The long curved eyelashes occur 150 times in a total of 470, being present twice as often in children under sixteen years of age. It is an infantile form, for this type of eyelash is shed at puberty and often replaced by a different type. It is generally dark brown to black. Short and straight occur equally often in men and women, but never in childhood. Short-curved is least represented, and occurs most frequently in men, never in children. Two apparently abnormal types were observed, one bent inward toward the eye, the other long and straight but hooked at the end. Inheritance of these characters having been neglected, there are no data for comparison, but one family tree shows interesting characters. Form and colour are not inherited together, but the inheritance of form is clearly to be seen.

**Black Disease and Sheep**—Pamphlet 19 of the Australian Council for Scientific and Industrial Research contains a concise account by Dr A W Turner of the nature and means of prevention of the much-dreaded black disease of sheep (infectious necrotic hepatitis). As a result of extensive investigations carried out by the Council and partly financed by the graziers themselves, it has been shown that this disease, which is responsible for such heavy losses in Australia, is largely preventable. An effective, but not costly, vaccine has been developed. This alone, however, will not prevent the incidence of the disease, for, as had already been suspected, the attack is dependent on previous injury caused by the liver fluke. The fundamental problem is, therefore, the elimination of this latter pest from Australia, and details of suitable methods for getting rid of fluke, such as drainage, treatment of marshy ground with copper sulphate, and drenching sheep with a mixture of carbon tetrachloride and liquid paraffin are described. Vaccination of sheep with the appropriate anti-black disease vaccine is also advised, and the necessity for burning infected carcasses strongly advocated. The cost of these operations is not prohibitive. Apart from labour, drenching and vaccinating sheep amounts to little over 2½d per sheep per annum, and considering the economic significance of the disease the outlay would seem more than justifiable.

**Power of the Adductor Muscle of Bivalves**—The power of the adductor muscle of the larger bivalves has often been remarked. Darwin referred to it in the case of the tropical *Tridacna*, and Vaillant in

1865 found that the absolute power of the adductor of *Tridacna elongata* ranged from 4919 gm to 7200 gm. per sq cm of section area of the muscle. Tadashi Tamura has now tested the power of the adductor muscle of thirty species of tropical marine bivalves, and has found it to range from 1071 gm in *Corallophaga* to 11,381 gm in *Chama* per sq cm of section area (*Science Reports, Tōhoku Imp Univ*, vol 4, Sept 1931). A comparison of the power of the adductor among different species of bivalves shows that the specific difference amongst lamellibranchs is far greater than in any other phylum of animals where such differences have been studied.

**Chromosomes of an Unfixable Dwarf Wheat**—In 1902 the late M Philippe de Vilmorin found two dwarf types in commercial wheats, but was unable to fix them by inbreeding, as the descendants always gave some tall progeny which bred true. Engledow and Wadham studied the problem and suspected chromosome irregularity. The solution has now been reached by Prof C L Huskins (*Jour Genetics*, vol 25, No 1), who investigated plants grown at Merton from seeds of Prof Engledow. It is shown that the dwarf plants in this unfixable wheat produce three main types of progeny: normals, dwarfs, and pigmies. The first two occur in ratio approaching 1:1, while the pigmies are rare. The tall have 42 chromosomes, the dwarfs 43, and the pigmies 44. In the dwarfs the extra chromosome is usually included in a trivalent in the pollen mother cell during meiosis, but is sometimes by itself or may form part of a quadrivalent or quinquevalent combination. Quadrivalents also frequently occur in the tall segregates. The extra chromosome in a dwarf is sometimes a long one and sometimes short, and the redistribution of these chromosomes produces smaller variations (noted by Engledow and Wadham) within the three main types which are due to the chromosome numbers. The main results are therefore similar to those obtained in the analysis of speltoid wheats and fatuoid oats.

**Germination of Teak**—Mr H R Blanford, of the Burma Forest Service, has paid a great deal of attention to the questions of germination, sowing, and planting of teak and other species. One of his latest papers on this subject is entitled "Experiments in Connection with Sowing and Planting Teak in Taungya Plantations" (*Burma For Bull* No 24, Silv Ser No 14, 1931) and is of very considerable interest. The paper deals with nursery experiments with teak seed, under the heads—treatment of seed and preparation of soil—position of nurseries—size of teak seed, direct sowing and transplanting of teak, and transplanting with stumps. Owing to the cheapness of seed in Burma in the past they have been content with a comparatively low germination percentage, but the importance of securing early germination would seem to justify extra treatment. It appears to have been finally established that it is moisture and not heat that is required for teak seeds sown during the hot weather. There does not seem to be much difference in seedlings originating from small and large seed, so that there is no reason for sifting the seed. Some valuable information has been obtained on the question of the comparison of the different methods of direct sowing and transplanting in a taungya plantation. The experiments apparently strongly confirm the very great advantage of planting as against direct sowing. The work carried out with teak stumps has not as yet reached a conclusive stage.

**Pliocene and Pleistocene Mollusca of California**—The main part of a "Catalogue of the Marine Pliocene and Pleistocene Mollusca of California and adjacent Regions", by U S Grant and H D Gale (*Mem San Diego Soc Nat Hist*, 1, 1931, pp 1036, pls 32), consists of a monograph of the species of Mollusca, but is preceded by a summary of the stratigraphy. It is pointed out that correlation by means of the percentage of extinct species may lead to erroneous conclusions. Thus some of the cold-water horizons seemed to be older than they really are, because of the apparently large proportion of extinct species, but with the fuller knowledge of northern faunas now available this percentage is known to be too high. It follows that faunas which lived under climatic conditions similar to those now existing in the neighbourhood will give the impression of being more like living faunas than those which lived during colder periods. Climatic changes are a fundamental cause of differences in faunas, and it is believed that these changes were widespread, especially in Pleistocene times, and are therefore of value in correlation over wide areas. The number of extinct species in the Californian Pliocene is already known to be much less than half the total number of species, and, when the living faunas of western Mexico and central America are better known, the number is likely to be further reduced. A number of striking similarities between Californian species and corresponding forms in Japan, the eastern United States, Europe, and Africa have been noticed. In California there appears to have been one well-marked sedimentary cycle in the Miocene and another in the Pliocene, and the beginnings and endings of these seem to have coincided with the beginnings and endings of the Miocene and Pliocene periods in Europe. It is believed that California remained relatively stable during the Miocene and Pliocene periods, and that the only widespread deformation that would upset the orderly sequence of sedimentary cycles did not come until the middle of the Pleistocene.

**Giant Pleochroic Haloes**—In 1920 Hirschi discovered abnormally large pleochroic haloes in the biotite of an Alpine syenite (radii, 54  $\mu$ ). Ten years later Wiman recorded the presence of similar haloes (55-60  $\mu$ ) in the biotite and hornblende of the Pre-Cambrian granites near Uppsala. As such haloes have not been generally observed, Wiman thought it improbable that they could be ascribed to the action of the long-range  $\alpha$ -particles from radium-C or thorium-C. See "The Age of the Earth", *National Research Council Bull.*, 80, p 187. It now appears from an examination of similar giant haloes in cordierite-gneiss from Madura, South India, that the hypothesis rejected by Wiman may, nevertheless, provide an explanation. At the eighteenth Indian Science Congress (*Proceedings*, p 309) M S Krishnan and C Mahadeven claimed to have shown conclusively that the dimensions of the giant haloes in cordierite correspond to the ranges 9.3 cm for radium-C and 11.5 cm for thorium-C in air. The full development and excellent state of preservation of the structures in these haloes is ascribed to the richness of the cordierite in radioactive nuclei-minerals and the long period of activity of the latter. The gneiss dates from early Pre-Cambrian times. The intensity of pleochroism in the haloes varies with the directions of light absorption in the cordierite.

**Auroral Heights in Canada**—The *Canadian Journal of Research*, vol 5, Sept 1931, pp 285-296, contains an important article on auroræ by J C McLennan, H S Wynne-Edwards, and H J C Ireton. On four dates in January and February 1931, photographs of auroræ (mainly of arc or band type)

were taken simultaneously from two stations, 46 km apart, alongside the Temiskaming and Northern Ontario Railway, the telephone system of which was made available to the observers. The main station (Onakawana) was at lat 51° N, long 81° W. A Kioogness auroral camera was used. The heights found ranged from 70 km to 130 km, the height of most frequent occurrence being about 95 km. These are a few kilometres lower than the corresponding heights found by Størmer in Norway. The geographical situation of the auroræ is shown on a map; the arcs and bands lie, as elsewhere, roughly at right angles to the magnetic meridians. The paper is enriched by beautiful reproductions of twelve pairs of auroral photographs.

**Correlation of Pressure and Temperature in the Upper Atmosphere**—The exploration of the upper atmosphere by means of sounding balloons equipped with apparatus for measuring pressure, temperature, and sometimes humidity, has been pursued to an increasing extent during the past twenty years, in the hope that this may lead to an understanding of the causes of the cyclones and anticyclones that are of such importance in governing the day to day variations of the weather. In Great Britain W H Dines showed that there is high positive correlation between pressure and temperature at any level between about 2 km and 8 km. W Van Bemmelen found a somewhat similar relationship for the upper atmosphere over Java, the principal difference being that the largest coefficients found there were not so large as those found for the British Isles, while they occurred higher up, between heights of about 8 km and 16 km. S Gopal Rao has now given an analysis of 185 soundings made at Agra in 1925-29, and compared the results with those obtained by Dines and Van Bemmelen (India Meteorological Department, *Scientific Notes*, vol 3, No 26, March 1931). He divides the material into two parts—winter and summer monsoon. The correlation coefficients for winter show a variation with height that agrees more nearly with the results of Dines, with the difference that the positive correlation disappears at 13 km instead of 11 km. The variation of those for the summer monsoon, on the other hand, agrees fairly well with that for Java. It appears that adjustment to conditions normal for a given latitude takes considerable time, considering that when the air supply to India is tropical, as happens at the height of the summer monsoon, conditions are found there such as are normal to a place near the equator. The gradual extension of such statistical inquiries to new regions is obviously desirable, and it is greatly to be hoped that the forthcoming Polar Year of arctic research may result in high latitudes receiving attention.

**Fundamental Physical Constants**—In two recent papers in the *Philosophical Magazine*, Dr W N Bond has developed a new way for reducing the experimental data used in connexion with determinations of the electronic charge ( $e$ ) and Planck's constant ( $h$ ), based on the observation that each group of experiments connects  $h$  and  $e$  by an equation of the form  $h = Ae^n$ , where  $n$  is either 1,  $1\frac{1}{2}$  or  $1\frac{2}{3}$ , according to the experiments, and  $A$  expresses the results of the measurements made. By taking two types of experiments with different values of  $n$ ,  $e$  and  $h$  may be found with previously unattained precision. By this method Dr Bond showed that Eddington's constant had a value of  $137.02 \pm 0.06$ , in excellent agreement with theory. The subject has now been taken up again by R T Birge, and in a note appearing in the *Bulletin of the American Physical Society* for Dec 6 he expresses the opinion that Bond's method

for evaluation of  $e$  is far more reliable than any direct determination, but disagrees with the way in which it has been followed up. In Birge's new calculation by Bond's method, the values of  $e$  and  $h$  are found to depend chiefly upon the value adopted for the specific charge ( $e/m$ ) of the electron, which he takes to be  $1.761 \times 10^7$ , remarking that this now seems well-established. It leads to a value of  $137.28 \pm 0.07$  for Eddington's constant, whereas if this were 137 exactly,  $e/m$  would have a value which he regards as improbably high.

**Constant Monochromatic Spark Illumination**—Forbes and Brackett, in the November *Journal of the American Chemical Society*, describe an apparatus by means of which a spark between metal electrodes can be maintained automatically constant over fairly long periods. The spark is struck between adjacent edges of two square bars moving in horizontal planes at right angles to each other, the bars being retracted by threaded rods passing through sleeves rotated by worm gears. In the case of zinc bars 400 mm long and 25 mm square, a life of one and a half hours per pair of edges was obtained with a 5 kw transformer operated on 35 amp and 110 volts. Measurements showing the constancy of the energy of emission from a monochromator for various metal electrodes are given, and also a simplified method of following the energy of emission through a measurement.

**Thermodynamics of Gas Reactions**—H. Scheibel, in the *Sitzungsberichte der Vienna Academy of Sciences*, Abt. IIb, vol. 140, p. 183, discusses in detail the calculation of gaseous equilibria by means of three types of formula: (1) the classical formula, with observed values of specific heats, (2) the formula making use of Nernst's chemical constants, and (3) the formula using the specific heats calculated by the quantum theory from the results of band spectra. The results show that the first type of formula gives the most reliable values, although it is based on

empirical results. The other two formulae, although they have a theoretical basis, involve so many approximations and (in the third case) uncertainties that it is not surprising that they do not, in general, show very good agreement with experiment. In the case of complicated molecules, for example, there is doubt as to the number of degrees of freedom involved and the extension of the Planck-Einstein function deduced for monatomic solids, to gases is not strictly justified by theory. It is to be expected that further experimental investigation will lead to improvement in this respect, when the third formula will probably be the only one in general use.

**Freezing Point of Platinum**—*Research Paper No. 326* of the U.S. Bureau of Standards, by Roeser, Caldwell, and Wensel, deals with the freezing point of platinum on the International Temperature Scale, measurements being made of the ratio of brightness of black bodies maintained at the freezing points of gold and platinum, the black bodies consisting of hollow enclosures of fused thorium oxide immersed in the fused metals. The metals were heated in air in a high frequency induction furnace to secure automatic stirring of the freezing metals and to avoid contamination from furnace windings. The International Temperature Scale adopted in 1927 by the General Conference of Weights and Measures defines temperatures above the freezing point of gold in terms of Wien's law of radiation, and the method adopted was therefore one which permitted direct reference to this scale. The mean value of the freezing point of platinum, obtained with two lots of pure platinum, two optical pyrometers and observations by three observers, was  $1773.5^\circ \text{C}$ . Other recent measurements when reduced to the International Scale, are  $1769.5^\circ$  by Hoffmann in 1924, and  $1762^\circ$  by Ribaud and Mohr. The paper also contains a list of fourteen previous independent determinations of the melting point of platinum.

### Astronomical Topics.

**Eclipse of the Moon of Sept. 26, 1931**—*L'Astronomie* for November contains a series of photographs of the partially eclipsed moon, also diagrams by M. Ananoff showing the distribution of colours on the lunar disc during the total phase. The most interesting point is that there was a region described as "Bleu-verdâtre" throughout totality, though it changed its position on the disc. Blue is not very often seen on the moon (witness the phrase 'once in a blue moon'), but the writer of this note recorded that part of the disc was of a decided blue colour in the eclipse of Oct. 17, 1902. Dawn ensued shortly after this, and it was of a pure blue colour, without any admixture of red, this probably had some connexion with the blue on the moon. A note, with a diagram, was published in *Observatory* for November 1902.

**Astronomical Society of South Africa**—Vol. 3, No. 1, of the *Journal* of this Society begins with a well-deserved eulogy of Rev. Fearon Fallows, the first director of the Cape Observatory, who died in 1831, aged forty-two years. His death was hastened by overwork and anxiety. In spite of grave difficulties, due to inadequate assistance and unsatisfactory instruments, he made a creditable beginning in the work for which the observatory has since become so famous, his wife took observations with the mural circle, since he was deprived of an assistant. This circle had been sent out to him in an unfinished condition, the steel collar not having been properly

attached. The article closes with the words: "May a long succession of His Majesty's Astronomers, and the people of South Africa, never forget how much they owe to the patient, self-sacrificing, and arduous labours of Rev. Fearon Fallows." An account follows of a large meteor seen to fall in 1838, the explosion being heard over a radius of 70 miles. A number of fragments were collected, some weighing 3-4 lb. This meteor is omitted from many lists of meteors seen to fall.

Four photographs of the total lunar eclipse of April 2, 1931, are reproduced. The gradation of shading at the edge of the shadow is well brought out. The fourth picture was taken during totality with exposure only two seconds, the limb is clearly visible, and some trace can be seen of the maria. The report of the comet section notes that this is the first report since 1916 that does not include the discovery of a comet in South Africa. Mr. Blathway spent 130 hours in searching for comets, but without success. A very complete series of observations of Encke's comet was made at Johannesburg.

Nova Pictoris is fading very slowly, and is still of magnitude 8.4. The light of the central star is nearly constant, but the components *B* and *C* are fading. Dr. Spencer Jones reports that the spectrum is of Wolf-Rayet type, but with a strong emission of unknown origin at 6087 Å. His conclusions as to the present condition of the star were communicated to the Royal Astronomical Society, and have already been noted in this column.

## Early Scientific Worthies of America

IN 1661, John Winthrop, son of John Winthrop the first governor of Massachusetts, visited England for the purpose of securing from Charles II a royal charter for Connecticut, of which colony he had himself for many years held the governorship. Born in 1606, he had travelled, and studied, was a capable physician, possessed a knowledge of chemistry and metallurgy, and had promoted the iron and other industries of the American colonies. Twice before he had visited England, but his third visit coinciding with the birth of the Royal Society, at a meeting of the Society in the old Gresham College in December 1661 he was chosen one of the members, and in May 1663, after the Society had secured its charter, his name was included in the list of original fellows.

Already known to many European men of science, after his return home Winthrop became the western correspondent of the Royal Society, and it was mainly through his letters from Newton, Boyle, Hooke, Barrow, and others, and the *Transactions* of the Society that the mathematicians and naturalists in the colonies learnt of the progress of science in Europe. Winthrop's active and useful life came to a close on April 5, 1676, and he was buried in King's Chapel, Boston, where his famous father and some of his distinguished descendants also lie.

Such, briefly, is the biography of the earliest of the scientific worthies of America, to whom Mr F E Brasch refers in two historical articles on the Royal Society of London and its influence upon scientific thought in the American colonies, published in the *Scientific Monthly* for October and November. When Winthrop lived, the colonies were still but sparsely populated, and the conditions of life could have provided little opportunity for the pursuit of knowledge for its own sake. Yet long before he died Harvard College was a flourishing institution, and, as Mr Brasch shows, with the growth of the college, the effects of the intercourse between the Royal Society and America, which began with Winthrop, were more and more fully felt, with advantage to both the Society and the colonies. To this intercourse may be traced, among other things, the founding of both the American Philosophical Society and the American Academy of Arts and Sciences.

Mr Brasch's review covers the latter half of the seventeenth and the whole of the eighteenth century, and in that period he recalls no fewer than eighteen

fellows of the Royal Society who were connected with American science in one way or another. Among these were Thomas Brattle, a successful merchant and treasurer of Harvard, whose astronomical observations of the comet of 1680 were of use to Newton and Halley, William Brattle, his brother, the first tutor of philosophy in the colonies, William Byrd, who sent plants and minerals to Sir Hans Sloane, John Leverett, president of Harvard, Cotton Mather, who corresponded with John Woodward and sent him fossils, Paul Dudley, Chief Justice of Massachusetts, who communicated to the Royal Society papers on natural history and is regarded as the first horticulturist in America, and John Winthrop (1681-1747), a diligent collector, to whom the fortieth volume of the *Transactions* of the Royal Society was dedicated.

Valuable as were the efforts of these individuals in furthering the claims and interests of science, of still greater importance was the work of Benjamin Franklin, John Winthrop (iv), Dr John Morgan, and David Rittenhouse, who were admitted to the Royal Society in the years 1756, 1766, 1765, and 1795 respectively. Franklin is rightly regarded as the foremost American man of science of the eighteenth century, and not the least of his services was the constant solicitude he showed when abroad for the reputation of his fellow-workers at home. He was "virtually the intellectual ambassador of his fellow-beings."

Mr Brasch calls John Winthrop (iv) the first real scientific astronomer and the first Newtonian disciple in America. Born in 1714, eight years after Franklin, Winthrop at the age of twenty-four years was chosen professor of mathematics and natural philosophy at Harvard, a post he held with distinction until his death in 1779. He introduced the study of fluxions, he established a laboratory for experimental physics, for more than thirty years he made astronomical observations, he contributed eleven papers to the Royal Society, and to him can be attributed the founding of the American Academy of Arts and Sciences.

Of John Morgan (1735-1789) it is sufficient to say that he was the founder of the first medical school in America, while David Rittenhouse (1732-1796), who as a boy drew mathematical figures on fences and barn-doors, planned the first observatory in the colony and was the successor of Franklin as president of the American Philosophical Society.

## The Physics Workshop at the Imperial College.

ON Wednesday, January 6, during the special session for members of the Annual Exhibition of the Physical and Optical Societies, Prof C V Boys, in the presence of about a hundred subscribers, presented Mr W J Colebrook, formerly superintendent of the physics workshop of the Imperial College of Science and Technology, with a cheque for £100 on the occasion of his retirement. Mr Colebrook had been connected with the workshop for forty years, and in addition he had acted during the War as workshop consultant to the War Office X-ray Committee, and from 1914 to the present time had been superintendent of the Air Ministry workshop. The testimonial represented the good wishes and appreciation of a large number of scientific workers.

During the course of an interesting address, extracts from which are subjoined, Prof Boys outlined the early history of the physics workshop, with which he himself had been closely associated, and described how he had 'discovered' Mr Colebrook

Lord Rayleigh, who occupied the chair, added that during the years in which he had worked at the Imperial College he had been impressed by the efficiency of Mr Colebrook's workmanship and his capacity for organising his department with a complete absence of friction and ostentation. Further appreciations were expressed by Lieut-Col K Edgecumbe and Mr Watson Baker, representing the British Electrical and Allied Manufacturers' Association and the British Optical Instruments Manufacturers' Association respectively, and the former presented Mr Colebrook with an additional cheque on behalf of fifty-seven exhibitors at the Annual Exhibition of the Physical and Optical Societies, of which he had been organiser during the twenty-one years since its establishment. Mr Colebrook, acknowledging the testimonials in an interesting and appropriate speech, expressed his gratitude for the invariably friendly relations which had always existed between him and those with whom he had worked.

In the course of his speech, Prof Boys said

"We have met to-day to express our appreciation of the valuable services which have been rendered by Mr Colebrook during the last forty years. During this time he has made us all his debtors on account of his industry, his good temper, his willingness and desire to help, and, above all, by his consummate skill as a craftsman.

"When I see now the magnificent collection of tools which in the present century has grown up under his guidance, and contrast it with the meagre equipment of my time, I feel that the early history of the workshop—which no one else but myself can give—and of the introduction of Mr Colebrook is of sufficient general interest for me to recount.

"About the year 1873, Prof Guthrie made out an order for a small general purpose lathe, but this order was stopped when it got to the museum, and the official answer, put colloquially, was—'Lathe? What can you possibly want with a lathe in a physical laboratory?' If you have anything which you want to be turned, let us have it and we will get it turned in the museum workshop.' Well, Prof Guthrie was Scotch and very persistent, and General Festing, R.E., the engineer in charge of the museum and workshops, was a delightful, genial, and jovial friend of all who came his way. The result was, skipping intermediate steps, that a little 4-inch Cotton and Johnson lathe was acquired, and, though a poor little thing, it was in constant use and proved itself invaluable.

"Coming now to the second chapter, about the year 1890, Prof Rucker and I felt that we must have something better, and it was left to me to select a suitable lathe, but with the strictest attention to cost. There was very little money, and we did not want to draw a second refusal similar to the first. I selected what I considered the best possible lathe for physical laboratory requirements that was not too expensive. This was the Barnes 5½-inch centre lathe, and after forty years I still consider that I

could not have done better. I got the identical lathe for myself a few years later, and this is all I have for my own use to the present day. It may be interesting to state that when Prof Mendenhall came to see me, he said—'Why, that is the lathe on which Rowland cut his famous screw—the screw of his diffraction grating machine.'

"Having now a suitable lathe, it was essential that there should be a skilled mechanic to use it and to protect it from misuse, and again I was asked to find him. I heard of Mr Colebrook, and got him to come for a preliminary discussion. I asked him to do something with the new lathe and with a file, and, being a bit of a mechanic myself, I saw with half an eye that his handling of these tools showed him to be a skilled craftsman.

"This was the time when I was preparing my apparatus for weighing the earth, which I did at Oxford. The main apparatus was made by the Cambridge Scientific Instrument Co., but much had to be done besides, and this construction was done partly by Colebrook (I must now drop the Mr) and partly by myself. It was then that I learned to appreciate not only Colebrook's skill but also his conscientious devotion to the work. About the same time I was photographing bullets, and I required a very perfect revolving mirror to analyse the sparks that I used in order to get one bright enough, small enough, and of short enough duration so that the bullet should not travel more than  $\frac{1}{16}$  inch while it was being photographed. I designed this to be made in dead-hard tool steel. Colebrook made it to perfection, and it was figured by Hilger. We ran this at 500 revolutions per second for ordinary use, but we did run it up to 1500 revolutions per second, at which it ran well. This is nearly twice the speed at which Foucault ran his mirror when determining the velocity of light, and my mirror would have shown the time taken by light to traverse the length of this lecture table. It was to Colebrook that I owed the success of this mirror."

### A New Method of Measuring High Frequency Voltages.

IN the *Elektrotechnische Zeitschrift* for Aug 13, L Pungs and H Vogler describe a new electro-optical method of measuring voltages of very high frequencies. In practice, some type of electrometer is generally employed, but with very high frequencies its readings are untrustworthy. The authors made a test on a good electrometer of a type usually employed, and found that up to one and a half million cycles per second it gave accurate and consistent results, but at twelve million cycles its readings were incorrect by errors lying between thirty and forty per cent. As these instruments are largely used in radio work for making investigations on the dielectric behaviour of insulating materials, it was necessary to find the cause of the inaccuracies and either correct their design or try to invent a new method. The errors of the instrument were found to be mainly due to the fact that its capacitance varied with its deflection, for this led to resonance effects which made the readings quite irregular.

The authors have found a practical solution applicable to many cases. They utilise the well-known Kerr effect in electro-optics, which has been studied carefully by many physicists. The physical basis of their method is to use a monochromatic source of light, a Nicol's prism as polariser, a cell containing nitrobenzene subjected to electric stress between two parallel metal plates, maintained at the voltage to be measured, and a second Nicol's prism as analyser. The field of view is first extinguished by crossing the prisms when the voltage is not applied. On applying

the voltage, light comes through owing to the Kerr effect. If the voltage be alternating, the intensity of the light is a periodic function of the time.

The authors obtain a mathematical formula for the mean intensity of the light passing through, showing that, on the supposition that there is no inertia effect, it is independent of the frequency of the alternating voltage. Making sine wave assumptions also, they prove that it is proportional to the maximum value of the electrostatic field. With the help of tables of Bessel's functions they calculate the maximum voltage, which can be found in terms of the mean light intensity. Since the mean light intensity is independent of the frequency, the instrument can be calibrated with low frequency voltage.

The main difficulties that had to be overcome in connexion with the method are, first, that the Kerr constant varies very appreciably with temperature. Hence unless the temperature remains constant it has to be measured and a correction applied. The calibration also depends on the intensity of the source of light, it is therefore necessary to specify accurately the source of the light. The calibration is only accurate for light of a definite wave-length. The authors, therefore, were led to develop a comparison method which enables a higher accuracy to be obtained.

In this method the Kerr arrangement is adjusted so that the field is dark with zero voltage, a photoelectric cell being employed. The voltage is then applied to the Kerr cell, and the illumination of a second photoelectric cell is adjusted to a balance by

means of an electric circuit. The high frequency voltage is then cut out and a fifty cycle voltage applied, and the electric circuit is adjusted until the balance is the same as before. In this way the effective value of the high frequency voltage can be found. The comparisons are made rapidly, so that the temperature of the Kerr cell remains practically constant and the necessity of applying a temperature correction is eliminated. So long as the colour of the light is the same when making the two comparisons, it is not necessary to know its wave-length.

According to results obtained by physicists, it can be assumed that up to frequencies of thirty million cycles per second the Kerr effect is free from inertia.

In this case the wave-length is ten metres. The authors suggest that it can probably be used down to five metre wave-lengths. They have used the method for voltages lying between 300 and 4000 volts. The highest frequency they used was twelve million cycles (25 metres). By using a Pulfrich photometer and applying a direct method they found that the error was 1 per cent when the applied voltage was 800 and 0.33 per cent at 1800 volts. With the photoelectric method the error was 2 per cent at 800 volts and 0.1 per cent at 1800 volts. This method has the disadvantage that the photoelectric cells and the amplifying apparatus have to be carefully screened.

### Annual Conference of the Geographical Association

THE Annual Conference of the Geographical Association was held at the London School of Economics, by kind permission of the director, Sir William Beveridge, on Jan 6-8. As usual, the Conference was well attended by delegates and members from all parts of Great Britain, and at some of the lectures the audience exceeded four hundred. A representative publishers' exhibition, in which twenty-six firms took part, was held in conjunction with the Conference. At the termination of the proceedings in London, according to established custom, a party of members spent the week-end in a country town, this year at Rochester.

Of outstanding importance was the presidential address by Sir Leslie Mackenzie, entitled "A Health Administrator's Attitude to Geography." The work of the medical profession deals increasingly with the prevention of disease as opposed to the cure of disease, and for the medical officer of health geography must be his guide, for geography is the study of the earth as the environment of man, and Sir Leslie referred to the "flowingly intimate" correlation between health conditions and geography. In Scotland the three million population of the Midland Valley contrasts with the 420,000 people of the Highlands—a reflection of relatively favourable and relatively unfavourable geographical conditions. A study of malnutrition amongst Highland school-children has shown an intimate connexion with bad harvests, which in turn reflect fluctuations in climatic conditions from year to year in a region where other geographical factors such as physiography and soil exercise a somewhat rigid control.

Coming to details, Sir Leslie pointed out that geographers have long emphasised the importance of aspect in influencing the distribution of natural vegetation and crops. It is equally important in determining health conditions. There are valley sides "half starved of sun for a million years" which must inevitably remain disease traps for their human inhabitants when compared with the opposite slopes of the same valleys. Further reference was made to the geographical methods of mapping distributions and of determining limiting factors in each case. There is need for the health administrator to follow these methods. What, for example, is the limit of distribution of tetanus in the soil of France? Is it coextensive with a certain type or certain types of soil? The widespread distribution of tetanus in Flanders soil was one of the great problems which had to be tackled by the medical service during the War. Modern developments, for example, in the field of transport must not be ignored by the medical officer, it has been shown, for example, that disease-bearing mosquitoes can be carried 12,000 miles by aeroplane. In short, the work of the health officer

provides a new *motif* for the study of geography and the employ of cartographical methods of studying distributions.

The work of the Conference included also an important joint discussion with the Historical Association on "What is Historical Geography?" Prof. C. B. Fawcett undoubtedly stated the main difficulty when he said that there are so few equipped with an adequate training in both geography and history, and that until students so equipped are forthcoming the present confusion is likely to continue. He referred to Sir Halford Mackinder as a historian who has become a great geographer, and has expressed the relationship between the two sciences by saying that every event occurs both in space and time and is thus the concern both of geographer and historian, though, of course, not all events are of equal importance to either student.

The discussion made it clear that many of the historians present were inclined to equate 'geography' to 'physical geography' and failed to appreciate the modern human geography. Thus, Dr J. E. Morris stated "A geographer can only introduce the subject, for, when he has told us all about climate and situation, environment and stimulus, geological conditions and rainfall, it remains for the historian to show how men have used their opportunities." There was clearly no appreciation of geographical synthesis, of the study of the environment as a living concrete whole, continually acting and reacting on the central figure of man. Similarly, Prof. F. S. Marvin referred to the natural factors, "the river, the mountain, or the sea", and was obviously limiting his conception to the factors of physical geography. On the other hand, Prof. A. P. Newton showed clearly that he represents a school of historians having a clear conception of the methods and value of modern geography. Prof. E. G. R. Taylor showed how a descriptive topographical introduction accompanying historical works has come to receive the label 'historical geography' for what should be merely the geography of history. Indeed, the whole discussion made it clear that both geographers and historians have been guilty of selfishness: geographers using some of the results of historians to further geographical knowledge, historians using fragments of geography here and there for the advancement of historical studies. A plea was made whereby the Geographical and Historical Associations might devise some scheme for the exchange of research data. Miss Jeffries Davis, editor of *History*, surprised many of her listeners by finding a common requirement of both historians and geographers outside the direct sphere of either—the early completion of the 'drift' edition of the geological maps of Britain.

Dr Gerhard Schott, the well-known oceanographer

of Hamburg, was the Association's principal foreign guest this year, and gave a lecture on the "Humboldt Current in relation to Land and Sea Conditions on the Peruvian Coast." Dr H R Ormsby lectured on the part played by the limestones in the human geography of France, and afforded thereby a delightful example of the broader conceptions which can be drawn from a study of the detail accumulated in her recent book on "France."

At the annual general meeting, Dr L Dudley Stamp reported on the progress of the Land Utilisation Survey of Britain, and referred to the urgent necessity of completing the Survey in the present year, so that the record for the whole country would be for 1931-32. He asked especially for volunteers (to communicate with him at the London School of Economics) to complete areas in Oxfordshire, Huntingdon, West Suffolk, Essex, West Sussex, the Isle of Wight, Gloucester, Leicester, and North Yorkshire.

Brigadier H S L Winterbotham gave the Association an account of new developments in the Ordnance Survey one-inch maps. Mr S A S Hozayen lectured on the Arab geographers, Mr J Fairgrieve dealt with several aspects of the cinema in schools, and the Association welcomed an old friend in Prof P F Kendall.

L DUDLEY STAMP

### University and Educational Intelligence.

CAMBRIDGE.—It is announced that Mr R H Fowler, fellow of Trinity College, and University lecturer in mathematics, has been appointed to the John Humphrey Plummer professorship of mathematical physics. Prof Fowler is distinguished for his theoretical investigations of the structure of the atom and related subjects.

LEEDS.—The University has received the legacy of £100,000 bequeathed to it for general purposes by the late Lord Brotherton. In conveying thanks to the executors for making the presentation in person and for their expressions of goodwill towards the University, the chairman of the Finance Committee stated that Lord Brotherton, during his lifetime, made gifts to the University amounting to £120,150, chief amongst which were £20,000 for the endowment of the chair of bacteriology and £100,000 for the building of a new library. The erection of the latter—to be known as "The Brotherton Library"—will be commenced shortly, the foundation stone already having been laid by Lord Brotherton himself.

Mr T H Blakeley has been elected to the Gas Research Fellowship endowed by the Institution of Gas Engineers, which has been rendered vacant by the appointment of the previous holder, Dr A H Eastwood, to the staff of the Joint Research Committee of the Institution and the University. Mr Blakeley has carried out an investigation into the thermal conductivity of materials used for the insulation of high temperature furnaces. As holder of the fellowship, he will undertake further research work in the University under the direction of the Livesey professor of coal gas and fuel industries, on the reactivities of carbonised fuels at high temperatures.

Two special lectures of the series dealing with aspects of biochemistry being given at the Chelsea Polytechnic, Manresa Road, London, S W 3, will be delivered by Dr Colin H Lea, of the Low Temperature Station, Cambridge, on Jan 28 and Feb 4, at 6 p.m. The subject of Dr Lea's lectures will be "Some Recent Advances in the Chemistry of the Fats." Further particulars can be obtained from the principal of the College.

TECHNICAL Colleges in Great Britain differ noticeably from one another in respect of their devices for maintaining close touch with the changing needs of the various industries which look to them for recruits or for the further education of persons already in employment. This remark is prompted by an inspection of a number of prospectuses for the current session. The Heriot-Watt College, Edinburgh, is conspicuous for the completeness of its system of associating itself with industrial firms. On its board of governors are representatives of printing and kindred trades and engineering employers' associations, coal owners and miners and building trades associations, local trade unions and the fermentation and pharmaceutical industries, and it has advisory committees for the printing trades (8), central mine-rescue station, engineering, mining, building, pharmacy, commercial studies, and stock exchange. The Royal Technical College, Glasgow, has on its committee on chemistry and metallurgy representatives of four firms and the president of the West of Scotland Iron and Steel Institute, and has representatives of firms or industrial associations on committees on engineering, textiles, building, navigation, pharmacy, bakery, and watch- and clock-making. The Technical College, Bradford, has on its college committee the presidents of the Chamber of Commerce and of the Trades and Labour Council. The Manchester Municipal College of Technology has sectional committees for textile industries, pure and applied chemistry, engineering and handicrafts and an advisory committee on industrial administration. Unfortunately, many prospectuses give no indication of the existence of any systematic check being applied to the tendency commonly to be found in teaching institutions in Great Britain to become too academic and out of contact with our industries.

### Calendar of Geographical Exploration.

Jan 24, 1616—Le Maire Strait

Two Dutch navigators, Willem C Schouten and Jacob le Maire, discovered the strait between Tierra del Fuego and Staten Island. They had sailed from the Texel on June 14, 1615, hoping to discover a passage to the South Sea south of Magellan Strait, since only members of the Dutch East India Company might sail either by the Cape route or Magellan's Strait. On Jan 29 the vessels were off Cape Horn, the southernmost point of the Tierra del Fuego Archipelago, which received its name from Schouten's birthplace, Hoorn. On their journey across the Pacific they discovered Dog Island, in the Low Archipelago, and Boscawen and Keppel Islands, between the Fiji, Tonga, and Samoan groups. They then touched the hitherto unvisited coast of New Ireland. They had hoped to reach the supposed southern continent, and made a survey of the north coast of New Guinea, thinking that this island might be part of Terra Australis. At Java their vessel was confiscated because it was thought that they must have used one of the forbidden routes. They were sent home on another vessel, Le Maire dying on the voyage home. His father, after two years' effort, secured recognition of the fact that a new strait, south of Magellan's, had been discovered.

Jan 26, 1621—The Gambia

Richard Jobson left Tenda, after having sailed up the Gambia river. There he had heard stories of a city in the interior the roofs of which were covered with gold. He concluded that this was Timbuctoo, but that city was really 1000 miles from Tenda.

Owing to the shallowing of the river when the dry season set in, Jobson was compelled to start his return journey on Feb. 10, and not for a century was any further effort made to reach the Niger river and inner Africa. Jobson had been sent out by a company formed in Britain in 1618 with the purpose of exploring the Gambia. Their first expedition was entrusted to Richard Thompson, the pioneer of British exploration in Africa. But attacks by the Portuguese, mutiny among his own followers, and the deadly climate resulted in failure, Thompson being murdered by his own men. Jobson escaped with his life, but the company was dissolved.

Jan. 26, 1903—Coats Land and the Weddell Sea

W. S. Bruce in the *Scotia* left Port Stanley, in the Falklands, on a voyage to the Weddell Sea for purposes of scientific examination, Dr. R. N. Rudmose Brown and other scientific workers accompanying him. The vessel was anchored off Laurie Island for the winter, and scientific work and sledge exploration were carried on. In November 1903 the *Scotia* left Laurie Island, the meteorologist of the party, Mossman, remaining behind with five companions. The *Scotia* proceeded to Buenos Aires and brought back a party of Argentine meteorologists, who remained with Mossman on Laurie Island, while the vessel steamed southwards, discovering Coats Land and reaching 74° 1' S in 22° W. The *Scotia* carried a line of deep soundings across a vast stretch of previously uncharted ocean, and corrected Ross's marking of a point "4000 fathoms, no bottom", to 2660 fathoms, the powerful undercurrent and the less perfected instruments of Ross having caused the error.

## Societies and Academies.

### DUBLIN

Royal Irish Academy, Dec. 14—J. M. O'Connor. The nature of the metabolic regulation of the body temperature, and its relation to temperature sensations. The oxygen consumption of rabbits under urethane anaesthesia in relation to the rectal, brain, and mean skin temperature is analysed statistically. When the animal is not shivering, the oxygen consumption as determined in short periods (about 6 minutes) is closely correlated with the rectal temperature and is not appreciably influenced by the dose of anaesthetic used. The results obtained coincide with values previously established under the influence of curare. When the animal is shivering, there is an additional consumption of oxygen, which rises as the skin temperature falls from 35° C to 28° C, after which it declines and disappears at a skin temperature of about 23°. These short period results were confirmed by the examination of 40-minute periods during which the animals' temperatures were maintained approximately steady at various levels. No influence of the head temperature could be demonstrated. It is further shown that when the surface temperature of an area of human skin is lowered to about 21° C its power of originating sensations of cold becomes faint or is obliterated. The evidence supports the view that 'chemical temperature regulation' is a reflex response of the muscles to sensations of cold.—Miss W. E. Frost. Observations on the reproduction of *Nyctiphanes couchii* (Bell) and *Meganyctiphanes norvegica* (Sars) off the south coast of Ireland. These two euphausiids are the species most abundant in the plankton of the waters off the south coast of Ireland. An account is given of their reproductive cycles, showing the seasonal occurrence and varying abundance of their larvae in the plankton,

a few notes are given on the distribution of the larvae, the reproduction of the two species is compared. Some remarks are made on the euphausiids included in the dietary of herring and mackerel taken off the south, east, and north-east coasts of Ireland, attention is directed to the fact that the larval as well as the adult forms had been eaten.

### PARIS

Academy of Sciences, Dec. 7.—The president announced the death of Sir David Bruce, *correspondant* for the Section of Medicine.—H. Vincent. Notice on Sir David Bruce.—Georges Perrier. Work carried out at the southern end of the Delambre base line, at Melun. The pillar carrying the line indicating the southern end of the Delambre base line (1792–98) has become an obstruction to traffic: it has been lowered below the surface of the road, with precautions to prevent alteration in the length of the base line.—L. Blaringhem, M. Bridel, and Mlle C. Bourdoul. The dominance of the starchy character in hybrids of the first generation of two varieties of pea (*Pisum sativum*).—Jean Rey. The invention of the periscope. A claim for priority.—E. Mathias. Forms of lightning. Theory of formation of lightning resembling a string of beads.—P. Vincensini. A transformation of isotropic congruences.—G. Tzitzéica. Quadratic curves.—F. Marty. The determination of periodic minimum surfaces.—Georges Calugaréano. The necessary and sufficient condition for the univalence of a holomorphic function in a circle.—Miron Nicolesco. Harmonic and subharmonic functions of  $p$  order.—Jacques Devisme. Some partial differential equations.—J. Karamata. The applications of some theorems of inversion to exponential summability.—B. N. Prasad. The convergence of the conjugated series of a Fourier's series.—Florin Vasilescu. A method of Rjabouchinsky having for its object the solution of the problem of Dirichlet, in view of the calculation of the velocity potential.—J. Leray. The slow movement of a viscous fluid in two dimensions limited by fixed walls.—Ch. Racine. The gravitation equations of Einstein.—B. Lyot. The photography of the solar corona apart from eclipses. A detailed account of the precautions found necessary to reduce the instrumental and atmospheric diffusion to a minimum and to amplify the contrasts of the negative. The first results, although imperfect, show that it is possible to follow the changes in the appearance of the interior corona between eclipses.—Ernest Esclangon. Remarks on the preceding note. Emphasising the importance of direct observations being possible on the solar corona.—Ch. Fabry. Remarks on the preceding note.—Jacques Métadier. The general equation of Brownian movement.—Henri Chaumat and Edouard Lefrand. The realisation of electrostatic machines.—A. Grumbach and F. Taboury. The discontinuous variation of the electromotive force of photoelectric batteries with coloured liquids.—R. Hocart and Mlle A. Serres. The magnetic properties and crystalline structure in the different varieties of anhydrous cobalt sulphate. Two varieties of anhydrous cobalt sulphate exist, both crystallised and of orthorhombic symmetry. Their crystalline networks have the same dimensions, but the different structures and change of structure run parallel with the change in magnetic properties.—E. Darmon and Mlle R. Peyroux. The action of boric acid and borax on the rotatory power of glucose, galactose, and fructose.—L. Jacque. The action of petroleums arising from the catalytic hydrogenation of coal-tar as stabilisers. The stability of mixtures of ethyl alcohol and petrol from petroleum is increased by the addition of petrol produced by hydrogenation of coal-tar light oil—

T Karantassis and L Capatos The action of ammonia and amines on germanium tetrachloride. Ammonia gives the compound  $\text{GeI}_4 \cdot 8\text{NH}_3$ . Germanium iodide gives addition compounds with amines containing 4-10 molecules of the base to one of the iodide—Martineau The oxidation of ethyl alcohol by air in the presence of carbon-copper catalysts. The preparation of a copper-coated carbon of high activity, capable of oxidising alcohol at  $66^\circ \text{C}$ , is described—Émile André and Charles Vernier The preparation of  $\alpha$ -phenylethylamine and its separation into its optical isomers—Sebastien Sabetay The synthesis of the *p*-alkyloxy-methyl-benzaldehydes—M Battegay, L Denivelle, and J Meybeck The *N*-chlorosulphonylamides and the *N*-chlorosulphonylsulphonamides—André Kling and Daniel Florentin The mode of action of scission catalysts in hydrogenation cracking of hydrocarbons with a polycyclic nucleus Details of the results obtained by cracking naphthalene and anthracene in the presence of various catalysts Anhydrous aluminium chloride proved the most effective catalyst—Mlle Eglantine Peytral A method of preparation of ketene By a modification of Wilmers' method gaseous ketene containing only 0.5-1 per cent of impurities (carbon monoxide and ethylene) can be collected over mercury—V Babet The organic remains and colthic rocks of the old sedimentary formations of French Equatorial Africa (basins of the Niari and Nyanga)—Breistroffer The Albian level in Chartreuse (Isère and Savoie)—Louis Barrabé The existence of three layers comparable with those of the Germanic Trias in the eastern Corbières—J Devaux The study of the infra-red radiation emitted by the terrestrial atmosphere A preliminary account of results obtained at the summit of the Pic du Midi (2860 metres) with a spectrograph containing a rock salt prism A band at  $10\mu$  appears not to be due to water vapour or carbon dioxide This is probably an emission band of atmospheric ozone—J de Lagaye The visibility of Mont Blanc at the summit of the Puy de Dôme A statistical study of the visibility, with a discussion of the influence of moisture, state of the sky, and barometer—Coulomb Certain rapid long waves (due to earthquakes), and in particular, the wave *PL* of O Somville—Marc Simonet The genetic and cytological study of the hybrid *Iris pallida*  $\times$  *Iris tectorum*—Comandon and de Fonbrune Rhythmic contractions in the pigmentary cells under the action of various poisons—M Fontaine and P Porter The proportion of calcium in the blood of marine fishes In marine fishes the ratio of the globular calcium to the serum calcium is of the same order of magnitude as in the higher vertebrates No relation has been found between the calcium in the serum and the nature of the skeleton, bony or cartilaginous—L Lutz The soluble ferments secreted by the hymenomycete fungi The alcoholic constituents of essential oils and the antioxygen function—A Paillet The morphological variations of the symbiotic bacillus of *Macrocephum tanacetii*.

## CAPE TOWN

Royal Society of South Africa, Oct 21—G Slater The glaciated surfaces of Nootgedacht, near Kimberley, and the upper Dwyka boulder shales of the eastern part of Griqualand West (Cape Province) The evidence in Griqualand West contributes notably to our knowledge of glacial erosion and sedimentation Nootgedacht is a classical area for the study of progressive erosion of the topographical features by land-ice The rock basin contains large outcrops of jointed diabase which display excellent examples of crag and tail phenomena showing in plan the stream-

line form The iceward limb increases in length with progressive decrease in height of the obstruction to ice-movement, and terminates at the crest of a sigmoid curve Abrasion was therefore the dominant form of erosion in the later stages of ice action The leeward limb is associated with 'pluck', more especially in the larger outcrops The section at De Kalk is a type example of the sedimentation of glacial detritus in water The hard bands of tillite-like material represent englacial substance from land-ice which has been deposited as cakes from floating ice.

## ROME

Royal National Academy of the Lincei Communications received during the vacation—L Labocetta Geometric generation of the function  $I x$  and of the other numerical functions,  $Fr x$ ,  $Om x$ ,  $R x$ , associated with it—G Scorza Dragoni Concerning a theorem of Rosenblatt The author's recent criterion of unicity for the solutions of a differential equation assuming definite values in pre-established points, which partly includes an analogous criterion due to Rosenblatt, is developed further—D Mercogliano The equations of the surface of Veronese—G Palozzi Correspondences projectively associated, in a point, to a surface—A Masotti Observations on the plane motion of a system of points in which the centre of the velocity is stationary—A Bellugi The gravimetric depression of Gattatico-Parma—A Baroni Measurement of the parachor applied to the study of the constitution of polysulphides, polyselenides, and mixed sulphur-selenium chains For compounds containing three atoms of sulphur or selenium, these measurements indicate a linear chain, which branches in the case of the tetrasulphide, and exhibits a ring of three sulphur atoms for the two isomeric diethyl pentasulphides, the latter have the structures,

—L Passerini and M. Baccaredda Researches on spinels (4) Sulphochromites of manganese and of cadmium Both manganese sulphochromite,  $\text{MnCr}_2\text{S}_4$ , and cadmium sulphochromite,  $\text{CdCr}_2\text{S}_4$ , exhibit a structure of the spinel type—G Natta and L Passerini Sulpho-salts having spinel structures Zinc sulphochromite belongs structurally to the spinel class and, given the small ionic radius of zinc, it may be assumed that the sulphochromites of other bivalent metals with ionic radii slightly greater than that of zinc possess the same lattice structure—Giulio Cotronei and Celso Guareschi Zoological constitution and grafting Experiments with Anura and Urodela (6)—M Ghiron Enzymes and immunity When the tubercle bacillus is grown in glycerin-broth containing a sterile glycerin suspension of an active lipolytic enzyme isolated from liver, an enfeebled strain of the organism is obtained Moreover, systematic inoculation of the same enzyme during the development of the tubercular process determines an arrest of such process at the first phase of the inflammatory process, which may be followed by cure without further progress of the lesion—G Mezzadrolì and E Varetton Action exerted on the development of silkworms by an open oscillating circuit of copper and zinc, functioning in proximity to a short wave-length radio oscillator Under the influence of these circuits the whole of the life-cycle of the silkworm is accelerated and its development is enhanced, the worms attaining increased robustness and weight Further, spinning is commenced earlier, and the yield of cocoons is augmented 10-15 per cent—P Pasquini Correlative differentiation of the crystalline lens and cornea in the development of anuran and urodele amphibians—

Ada Bolaffi Investigations on the lipoids of human tumours, particularly on the sulphophospholipids of the tumour. All the neoplastic tissues—human or otherwise—investigated by the author exhibit distinct analogies in their lipoidal constitution. They invariably contain a complex sulphophosphorated lipid extractable by means of acetone of specific gravity 0.85, but, if pure, insoluble in the anhydrous solvent. This lipid, which is moderately concentrated in the tumour, probably exhibits a constitutional character specific for each tumour, and represents a substance to some extent characteristic, if not quite specific, for neoplastic tissue. That occurring in human tumours is probably identical with the so-called jecorin.

## Forthcoming Events

### Societies

#### FRIDAY, JANUARY 22

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—Sir Arthur Keith Malformations of the Human Body considered from a New Point of View (Hunterian Lecture)

SOCIETY OF CHEMICAL INDUSTRY (Liverpool Section) (jointly with Manchester Section) (at Liverpool University), at 6—Dr A. E. Dunstan Liquid Fuels, To-day and To-morrow (Jubilee Memorial Lecture)

ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Sir Arthur Eddington The Expanding Universe

#### SATURDAY, JANUARY 23

MATHEMATICAL ASSOCIATION (London Branch) (at Bedford College for Women), at 3—A. R. Green Some Interesting Practical Problems in Elementary Geometry

#### MONDAY, JANUARY 25

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—Sir Arthur Keith Malformations of the Human Body considered from a New Point of View (Hunterian Lecture)

ROYAL SOCIETY OF ARTS, at 8—Capt O. A. Barrand and G. A. Green Life Saving Appliances on Merchant Ships (Thomas Gray Lectures) (2)

#### TUESDAY, JANUARY 26

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15—Prof C. A. Edwards The Progress of Research relating to Physical Metallurgy (2)

#### WEDNESDAY, JANUARY 27

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—Sir Arthur Keith Malformations of the Human Body considered from a New Point of View (Hunterian Lecture)

BRITISH WOOD PRESERVING ASSOCIATION (at 29 Lincoln's Inn Fields), at 6—K. St. G. Cartwright Diseases of Timber

ROYAL SOCIETY OF ARTS, at 8—Noel Heaton The Permanence of Artists' Materials (Lecture)

#### THURSDAY, JANUARY 28

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15—Prof H. G. Cannon Feeding and Digestion in Invertebrates (2)

#### FRIDAY, JANUARY 29

ROYAL ASTRONOMICAL SOCIETY (Geophysical Meeting), at 5—Prof E. V. Appleton Upper Air Ionisation

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—Sir Arthur Keith Malformations of the Human Body considered from a New Point of View (Hunterian Lecture)

### Public Lectures.

#### FRIDAY, JANUARY 22

IMPERIAL COLLEGE OF SCIENCE (Royal College of Science), at 5.30—Dr T. M. Finlay The Evolution of Landscape Mountains (Swiney Lectures) (8)

UNIVERSITY COLLEGE, LONDON, at 5.30—Prof H. A. R. Gibb The Expansion of the Arabs, A.D. 600–750

#### SATURDAY, JANUARY 23

HORNIMAN MUSEUM (Forest Hill), at 3.30—M. A. Phillips In the Haunts of the Sea-Birds

#### MONDAY, JANUARY 25

KING'S COLLEGE, LONDON, at 3—C. J. Gadd Assyrian Dealings with Israel

GUY'S HOSPITAL (in Physiological Theatre), at 5—Prof J. M. W. Morison The Use of X-Rays in Physiological Investigations (2) Respiratory Movements

KING'S COLLEGE, LONDON, at 5.30—Prof S. H. Hooke The Myth and Ritual of the Old Testament and the Cultural Patterns of the Ancient East (1)

IMPERIAL COLLEGE OF SCIENCE (Royal College of Science), at 5.30—Dr T. M. Finlay The Evolution of Landscape Glaciers and Land Sculpture (Swiney Lectures) (9)

#### TUESDAY, JANUARY 26

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5.15—Dr R. A. O'Brien The Preparation, Testing, and Use of Antitoxin (2)

KING'S COLLEGE, LONDON, at 5.30—H. A. Sieveking Peak Load and Energy Storage (1) (Succeeding Lectures on Feb. 2 and 9)

#### WEDNESDAY, JANUARY 27

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4—Dr R. Fortesque Fox The Rise of the Conception of Rheumatism as a Social Problem

SCHOOL OF ORIENTAL STUDIES (jointly with Royal Anthropological Institute), at 5.15—Prof C. G. Seligman Races of Africa

IMPERIAL COLLEGE OF SCIENCE (Royal College of Science), at 5.30—Dr T. M. Finlay The Evolution of Landscape Britain during the Ice Age (Swiney Lectures) (10)

BELFAST MUSEUM AND ART GALLERY, at 8—A. J. B. Wave Linen Damask

ESSEX HALL (Essex Street, W.C.2), at 8—Dr F. H. Hayward The Message of J. L. Tayler (Tayler Memorial Lecture)

#### THURSDAY, JANUARY 28

SCIENCE MUSEUM (South Kensington), at 4.30—Capt C. J. P. Cave Clouds

KING'S COLLEGE, LONDON (at 16 Russell Square, W.C.1), at 6—S. P. Turin Economic Conditions in Russia To-day (2) Unemployment in Russia

#### FRIDAY, JANUARY 29

IMPERIAL COLLEGE OF SCIENCE (Royal College of Science), at 5.30—Dr T. M. Finlay The Evolution of Landscape The Desert (Swiney Lectures) (11)

#### SATURDAY, JANUARY 30

HORNIMAN MUSEUM (Forest Hill), at 3.30—Dr A. I. Richards Women's Life and Work in a Central African Tribe

## Official Publications Received.

### BRITISH

University College of Wales, Aberystwyth Welsh Plant Breeding Station Self- and Cross-Fertility and Flowering Habits of certain Herbage Grasses and Legumes, together with Studies in Bulb Development and Spikelet Characters in *Arrhenatherum* (Series H, No. 12, Sessions 1921–1930) Pp. 240+2 plates (Aberystwyth) 2s

The British Mycological Society Transactions Edited by J. Ramsbottom, B. F. Barnes and H. Wormald Vol. 16, Parts 2 and 3, December 18 Pp. 89+208 (London Cambridge University Press) 15s

Canada Department of Mines Branch Chrysotile Asbestos in Canada By James Gordon Ross (No. 707) Pp. x+146+34 plates (Ottawa F. A. Acland) 25 cents

Torquay Natural History Society Transactions and Proceedings for the Year 1930–1 Vol. 6, Part 1. Pp. 82 (Torquay)

Department of Scientific and Industrial Research Building Science Abstracts Vol. 4 (New Series), No. 11, November Abstracts Nos. 2010–2247 Pp. 367+402 (London H.M. Stationery Office) 9d net

Museum and Public Gardens Administration Report 1105 M.E. Pp. 18 (Trivandrum)

County Borough of Southport The Fernley Observatory, Southport. Meteorological Department Report, and Results of Observations, for the Year 1930 By Joseph Barendell Pp. 28 (Southport)

- New Zealand Department of Lands and Surveys Annual Report on Public Domains and National Parks of New Zealand Pp 8 Annual Report on Scenery Preservation for the Year ended 31st March 1931. Pp 8 (Wellington, N.Z. W. A. G. Skinner)

## Exposition and Authority.

IT is somewhat strange that during General Smuts's recent visit to Great Britain so little attention has been directed to his constructive Sidgwick Lecture on "Democracy" at Newnham College, Cambridge, two years ago, almost every word of which has been underlined by current events "Statesmen are not enough We want to-day the scientific spirit in human affairs" 'It ought to be recognised that the scientific political expert is a necessary institution in national government Great party disputes which threaten the tranquility of the progress of the State should be remitted to a body of experts, where personal character and reputation confer exceptional authority on them, and whose recommendations should be available as a guide for public opinion and the Government"

The constructive truth of these words is attested by most of the inquiries which have been made in Great Britain in recent years, such as that conducted by the Coal Commission in 1926, the Macmillan report, with its warning on the necessity for deliberate planning in the sphere of finance and industry, in place of undirected natural evolution, and the Report of the Committee on Industry and Trade High authorities like Sir William Beveridge maintain that the solution of our unemployment problem is much more a matter of thought and organisation than of money Even political leaders agree on the necessity for closing the dangerous gap between knowledge and power which seriously threatens the continuance of our civilisation, although political events provide an almost unbroken sequence of disregard for facts and scientific method

For this position, as pointed out in recent articles in NATURE, politicians are not alone to blame Alike in domestic and in imperial affairs the scientific community has missed repeated opportunities of active participation in the framing of national and imperial policy, and even now the efforts of the British Science Guild to assess the value of the contribution of science to our national welfare and the potentialities of science in the evolution of a better order of society are largely unsupported

The indifference of politics to facts and its dependence on narrow prejudices are paralleled by the apathy of scientific workers themselves towards public affairs The situation here is the very reverse of that obtaining in Soviet Russia, where, as in Italy, there is danger that political

considerations may have undue influence on the selection of candidates for a scientific post. In Great Britain a scientific worker who is concerned about the social consequences of the application of scientific discoveries, or takes any active part in public affairs, either in a civic or municipal or national sphere, is apt to find himself regarded askance by his fellow-workers, and his candidature for important professorial posts probably would not be encouraged.

This attitude alone would largely account for the political impotence of scientific workers, which is well illustrated by their inability to return to Parliament, even in a university constituency, a candidate such as Major A. G. Church, who has rendered eminent services to the cause of science in Parliament and won general respect from all parties. Scientific workers at present form merely a disunited section, even in university constituencies, and until their interest in public and professional affairs is sufficiently strong to support united and representative professional associations their political impotence is likely to continue.

Indifference to public affairs finds further expression in certain criticisms levelled against the centenary meetings of the British Association. It has been objected that attempts to provide a general interpretation of science or of scientific topics in the presidential address are misleading to the public and not representative of the views of many scientific workers. Such criticism overlooks the fundamental need for an adequate interpretation of the mission of, and place of, science in human life and affairs and the limited opportunity which at present exists for such an exposition. So few, indeed, have attempted the interpretation in terms which the general public can understand, that it seems ungenerous to criticise those who have made the attempt. The general appreciation which was given to such addresses as Sir William Bragg's on "Craftsmanship and Science" and that of General Smuts are indication enough of their value.

A further objection that the publicity achieved by the British Association would be better attained by organising a more effective service of scientific news for the Press contains a valuable suggestion, but ignores the value and appeal of such a representative gathering of scientific workers in focusing public attention. No scientific meetings throughout the year, whatever their intrinsic merit, can hope to be given anything like the share of public attention that the British Association meetings receive. A visit of an eminent foreign man of science to Great Britain commonly remains un-

noticed by the Press, and few indeed are the scientific lectures which receive more than the briefest paragraph in the daily Press.

This cannot be attributed to the lack of able expositors when all allowance is made for variations in such powers. The clearest lecturer on science receives no greater share of attention than the most famous professor, who finds it difficult to lecture in terms other than those which are intelligible to advanced students alone. Nor can we blame a lack of able writers, for their opportunities are restricted by the modern insistence upon a name or sensationalism. If the ability to express the results of their researches in language which can be generally understood is not widespread among scientific workers, there are, at all events, more competent writers on science than opportunities for their expression.

The difficulty is aggravated because, even in the scientific community, comparatively few have realised the profound difference between genius for research and ease of exposition, and the need for authoritative exposition. It is rare indeed for the two powers to be combined in the one individual. The most casual reading of scientific papers or attendance at scientific lectures reveals that a man may be an outstanding authority and investigator in a particular branch of science and yet unable to give a lecture that can be understood by ordinary people, or write an article or paper which is fully intelligible even to research workers in his own field. The extent to which 'scientific' jargon has invaded all scientific journals is itself a consequence of the general lack of expository powers among scientific workers.

The existence of jargon, which is usually an indication too of loose thinking, is a further barrier to the task of disseminating the knowledge of science in the general community, and the latter task is one which urgently demands fulfilment, if, when scientific workers are able to make representations on national or imperial policy, their representations are to receive a fair hearing. Scientific workers must realise that trained minds devoted to the exposition of the results of scientific discoveries and their application are as essential as minds devoted to the acquisition of fresh facts and discoveries themselves, and scientific workers must be prepared to recognise and honour those who devote their time to the task of exposition and interpretation.

Mischief enough has been worked in the past by relying upon lay interpreters of science. The expositor required to-day must himself have had a

scientific training, be steeped in scientific principles and methods, and able to assess facts and values, and to interpret them in language understood by the common people. His authority is derived not so much from original scientific investigations of his own as from his power of comprehending his subject, assessing values, and understanding his public. In such exposition he will require the same qualities of mind and the unswerving loyalty to truth which his brother worker requires in his laboratory researches. Exposition is an art, and the imagination of mankind will only be fully touched by the achievements of science, and man roused to a wider application of scientific method, when innumerable artists of science, great and small, in utter fidelity to truth—to science as to life—have made plain its mysteries in words understood of all.

The formidable prejudices which exist against the expositor, who is commonly confounded with the demagogue or propagandist, are found even more among scientific workers than among the general public and the Press. Carlyle's assertion is uncomfortably true of the general scientific community: "Man is and was, always . . . much readier to feel and digest, than to think and consider. Prejudice, which he pretends to hate, is his absolute lawgiver; mere use and wont everywhere leads him by the nose." The prejudice of the scientific worker against participation in public affairs, and the prejudice of public and Press against the contribution of scientific workers who are disposed to public service, are mainly responsible for the gap between knowledge and leadership and the serious lag which has already developed between our rapid scientific advance and our stationary ethical development. These are among the prejudices which endanger the continuance of civilisation and which, as Sir Arthur Keith has warned us, must be mastered as a condition of its survival. The prejudice against exposition may be only a contributory cause, which hinders the task of educating the community as to the value of the contribution of science to the progress and well-being of society and its vast latent possibilities for the evolution and planning of a more balanced order. Interpreters of the right type will never be forthcoming in sufficient numbers until scientific workers are willing to accord to them honour where honour is due and to assist them by sympathetic and not unfriendly criticism. Fundamentally, the education of public opinion in this matter is a responsibility which scientific workers cannot evade.

While the ultimate solution may be found in education, we cannot wait on that slow process

alone. Already industry is showing the way, even in Great Britain, to relate leadership and knowledge, and scientific workers must address themselves not only to the task of educating public opinion on the importance of this issue, but also must increasingly show by the force of example the value of the contribution which science makes to human welfare. Through their position in industry, and through their professional organisations, scientific workers have already opportunities of bringing far greater influence to bear on public affairs if they would but forget their prejudices and unite for common action. Nor should the existing organisations be inadequate to secure that the profession of science be represented in Parliament by those competent to exercise the authority which is combined with knowledge, provided there be the will to this end. A wider use of existing opportunities by scientific workers should do much to close this gap and disarm the prejudices of the public and Press against the authority of science, and it is unlikely that any more important opportunity for publicity and service could be found than those afforded by just those representative gatherings of scientific workers among which the British Association meetings are pre-eminent.

### Science and Human Experience.

*Science and Human Experience* By Prof Herbert Dingle. Pp 141 (London: Williams and Norgate, Ltd., 1931) 6s net.

IN addition to the renowned protagonists of mathematical physics and cosmical astronomy, of whom Eddington and Jeans are the best known in Great Britain, but of whom also many others are recognised, for example, De Sitter of The Hague, Max Planck of Berlin, H. N. Russell of Princeton, E. A. Milne of Oxford, Bohr and Heisenberg of Copenhagen, not to mention other well-known names, such as R. H. Fowler, C. G. Darwin, the Thomsons, and many more, there has now arisen one who apparently is well acquainted with the work of all these geniuses, but finds it possible to differ from them in several important particulars, and with a cultivated historic sense to review the progress of physics from the days of Copernicus and Galileo to the present time. This writer is Dr. Herbert Dingle, honorary secretary of the Royal Astronomical Society, and assistant professor of astrophysics at the Imperial College, South Kensington. He has written a compact book, mainly on the philosophy of physics, but incidentally on the philosophy of science in general.

He claims to have written it, not for philosophers, who have technicalities of their own which he does not pretend to criticise, but for scientific men themselves. Naturally he deals primarily with mathematics and physics, but hopes that his treatment will be applicable and useful in all departments of science, the unity of which he thinks is far more important than their differences. For he has a

"strong conviction that the boundaries which separate the physical, biological, and psychological sciences are only temporary conveniences which will one day disappear, perhaps as completely as the boundary between chemistry and physics has already done"

He says:

"Historically, Science is a special kind of philosophy, and indeed the inquiry into the nature of Science . . . must be a metaphysical inquiry"

"The unspecialised thinker [he says] is most conscious of the activities of Science through the inroads which it makes into his æsthetic, moral, and religious ideas"

This last fact it is perhaps which has led to the almost universal interest in the great questions of cosmogony. The ordinary man

"wants to know, perhaps with mingled hope and fear, how much farther Science can go in prescribing the character of the world in which his lot is cast. He is interested to know that the universe is a bigger thing than his forefathers imagined, but he is still more interested in the question whether it is a better thing. He wants to know what this Science is in itself, what power for both construction and destruction is given to it, so that he may employ it in building his own intellectual habitation on a foundation which it is powerless to undermine. It is towards the solution of this problem that in this book I shall attempt to make a preliminary contribution"

Prof. Dingle evidently thinks that science can be of use or of harm in non-scientific domains, such as those of art, criticism, and religion, and he deals with these in an illustrative kind of way in the last three chapters of the book. Apart from this, and speaking as a physicist, he says

"The book has two purposes. In the first place it proposes an interpretation of the present position of physics, which seems to me to make rational what at first sight appears fantastic. The second purpose of the book is to provide, for the ordinary intelligent reader, an account of the remarkable changes in recent physical thought which have excited so much general interest. The new ideas [did not arrive] as a bolt from the blue, destroying at a blow the familiar beliefs of the past. They emerged gradually from the thoughts and labours of former generations, and now that they have come to light we can recognise in them

the natural blossoming of seeds of thought planted long ago"

This gradual evolution is one of the things Prof. Dingle tries to demonstrate.

Evidently the book is one that must be taken seriously. In so far as the author opposes the presentation of some of the ideas of men whom nevertheless he greatly admires, then, so long as he fully understands the meaning of their statements, he will be performing a useful and much needed purpose, for it is quite unlikely that the new physics as generally promulgated is right in every particular, and yet there are very few who have a knowledge which renders them competent to criticise.

It is not for a reviewer to attempt to decide which side is right and which is wrong in this battle of giants. He can but direct attention to the philosophic controversy which is here raised in a well-informed and polite and far-reaching manner with at least one example to illustrate any general statement.

The author starts off with the definition of the field or scope of science. He does not mean to exclude other branches of human knowledge from full attention, but he would exclude them from what he means and understands by 'science' in the strict sense. The definition runs thus:

"What, then, do we mean by Science? I take it to be *the recording, augmentation, and rational correlation of those elements of our experience which are actually or potentially common to all normal people*,"

and every word is evidently carefully weighed. In connexion with this definition, he emphatically contends that the experiences susceptible to scientific treatment must be 'common' experiences, not individual. He goes on to explain what he means by 'potential experiences', and also what he means by 'normal people', this last part of the definition giving him some trouble. Some readers will protest that this definition of the term 'science' is needlessly narrow, but when interpreting the author's contentions and occasional limitations, his definition should be borne in mind.

All this is introductory to the main theme of the book, which begins with interesting quotations from Copernicus and Galileo, and then goes on to criticise the attitude of Newton. In Galileo's view, says the author, the whole of objective Nature was susceptible of mathematical interpretation, and this he likens to Sir Arthur Eddington's limitation of physical science to pointer readings and metrical qualities. It is pointed out, however, that things

which Galileo would have treated as non-metrical, and therefore of the nature of secondary qualities, were after all susceptible of measurement, as illustrated for example by Newton's treatment of colour, so that the metrical world is more comprehensive than Galileo conceived it to be. Moreover, there are many undoubted parts of science which are non-metrical.

After a criticism of Newton's philosophy, Prof Dingle proceeds to consider the two great methods of scientific advance, one being *abstraction*, the other *hypothesis*. Physics has proceeded mainly by abstraction, biology and chemistry perhaps mainly by hypothesis. He has interesting things to say about these two methods. Abstraction proceeds mainly by subtracting from observed phenomena everything that can be regarded as non-essential, whereas hypothesis adds to observed phenomena something—it may be a guess—which is not displayed by the phenomena themselves. The atomic view of chemistry, for example, and the biological origin of species, are hypotheses. When a hypothesis is verified it becomes a *fact*, and science is enriched. There is another kind of hypothesis which can never be verified. These are serviceable for correlation, and can be justified because they do correlate a mass of phenomena. Such hypotheses may be regarded as tools, whereby facts and relations can be established. If an event is outside experience it can enter science only as a tool.

"As biologists it does not matter to us whether the higher forms of life actually emerged from the lower ones or not. The hypothesis that they did so emerge correlates our observations, as well as a conception as it would do as a reality, and we can therefore employ it so long as it continues to be of value."

Hypotheses are unverifiable when they refer to events which took place in the past, such as the origin of the solar system, for example. But they also may be unverifiable if they cannot be observed, like the formation of atoms from protons and electrons, or the whole of ultra-microscopic physics. Such hypotheses may nevertheless have a correlating value, and may thus ultimately be justified.

Prof Dingle illustrates the introduction of hypotheses into physics by three stages—one of 1687, by Newton himself, where he opposes all hypotheses as not deducible from the phenomena, the second stage, 1796, from Laplace, where he presents the nebular hypothesis with diffidence, as one which though highly probable is not the result of observation and computation, the third is from Eddington, 1926, where he regards the

macroscopic equations as 'useful tools', and the microscopic view as containing "the real truth as to what is actually occurring". Prof Dingle, after summarising the three stages—impermissible, highly probable, the real truth,—goes on to say that the whole microscopic scheme of physics belongs to the class of events the unobservability of which is part of their essential nature, and which therefore we presume can only be regarded as a hypothesis that is used for purposes of correlation.

The second law of thermodynamics he takes as an interesting example of the parallelism between abstractions from observation and the elaborations of the atomic hypothesis. It was originally formulated as representing deductions from large-scale phenomena, from which it is an abstraction, but it has now been formulated as having complete universality of application to the hypothetical atoms.

In Chap. iv the author takes as an "extremity of abstraction" the theory of relativity. The following quotation may serve to illustrate.

"The net result of Einstein's great theory, then, is that we can now regard the whole mechanical and electro-magnetic phenomena of Nature as a manifestation of the characteristics of one abstract medium—space-time, or ether, or whatever else we care to call it. The Newtonian conceptions of space, time, mass, gravitation, momentum, as well as energy and electric and magnetic forces, all take their places as specified peculiarities of this medium. To Newton, space and time were the stage on which the drama of forces and motions was played. To Einstein, the drama is merged into the stage, the play is the scenery. Abstraction can hardly go further. It has made the diverse phenomena of Nature into a universe, but at the expense of all individuality. The world is united, but featureless."

In Chap. v Prof Dingle deals with the "extremity of hypothesis", which he illustrates by the quantum theory. The emission and absorption of light are thereby 'explained' on a basis of a solar-system structure for the atom, subject to essentially arbitrary conventions.

"The electron is not something imaginable, but a pure thought-structure. It is therefore useless, and even positively harmful, to try to picture it. Relativity is abstracted from our experience of phenomena, it surprises us because it reveals possibilities of experience which we never contemplated. The quantum theory surprises us because it reveals impossibilities of experience which we never contemplated, we thought we were justified in extending to atoms the abstractions discussed in relativity, and we find that we were not."

In Chap. vi the author deals with "Experience

and Physical Theory", or what he calls "The common-sense of it all"

We have thus summarised the first half of the book, which now begins to get very interesting for the ordinary reader. In Chap. vii the author controverts Eddington's limitation of science to the metrical elements of phenomena, claiming that those concepts are not entitled to a monopoly of the realm of science. In the next chapter he attacks the great writers on the question of determinism, or rather indeterminism, as applied to atomic phenomena, and has some illuminating remarks on uncertainty and probability. The remaining chapters deal with "Science and Art", "Science and Criticism", "Science and Religion", subjects of which a treatment is evidently of intense importance to all except the unduly specialised, if they are dealt with (as they are) in the light of great and competent physical knowledge. These chapters contain a wealth of illustration from literature, and are very interesting and suggestive. Whether one wholly agrees with the author or not, the book is an achievement of first-rate value.

OLIVER LODGE

#### Progressive Entomology.

*Recent Advances in Entomology* By Dr A. D. Imms (The Recent Advances Series) Pp viii + 374 (London J and A Churchill, 1931) 12s 6d

IF the quantity and quality of published work is a safe criterion of the vitality of a science, entomology is showing no apparent signs of decay. On the contrary, it is displaying all the symptoms of a normal and vigorous growth. So intensively is research being prosecuted on both the pure and applied sides, that it is becoming increasingly difficult for the individual to keep himself conversant with the various advances that are being continually made. More and more the field of experimental activity is being enlarged in the search of new facts that may be utilised in man's struggle for ascendancy over the insect hordes that frequently threaten his very existence. At the same time investigation of purely morphological problems proceeds apace, unravelling the complexities of insect structure and function and shedding new light on the problems of relationship and ancestry. In the interests of further progress it is essential that the results of this vast volume of work should be submitted periodically to critical review and analysis.

For the successful accomplishment of such a task Dr Imms would appear to be the logical choice, in

that he brings to bear upon the work a mind that has been abundantly enriched, both by the diversity of his own researches and by an intimate acquaintance with the general mass of entomological literature that is wellnigh unsurpassed. No matter what the individual's attitude to the subject, entomology, may be—general student, investigator, or teacher—all will profit from the careful perusal of this book, in which the difficulties, so far from being shunned, have been courageously tackled and rendered attractive by reason of a consistently lucid exposition.

In virtue of the subject matter of the book, the account of it must necessarily be in the form of a review of reviews. The 'advances' are classified under morphology, metamorphosis, palæontology, sense organs, coloration, ecology, parasitism, and biological control. In the province of morphology the author discusses the various theories of the segmentation of the insect head, the homologies of wing-venation, and the probable derivation of metameric appendages from the biramous limbs of the higher Crustacea.

So far as metamorphosis is concerned, no satisfactory explanation of diverse larval types had materialised until Berlese emphasised the existence of three distinct embryonic phases—protopod, polypod, and oligopod—with which the principal larval types appear to conform. Larvæ emerge from the egg in different stages of morphological development. Those of holometabolous insects are hatched in a more primitive condition than the hemimetabolous. Consequently, there supervenes a highly specialised cœnogenetic development, which demands a pupal period of quiescence, during which transformation to the adult occurs. In insects, as in other animals, ontogeny is a recapitulation of phylogeny. But it must be remembered that ontogeny is subject to abbreviation and to masking by secondary non-ancestral features.

In the field of palæontology the researches of Handlirsch and Tillyard have considerably extended our knowledge of the probable trend of evolution in the principal insect orders. It is now generally accepted that the Exopterygota arose from the Palæodictyoptera of the Upper Carboniferous. The Endopterygota, on the other hand, would appear to have a tri-radiate ancestry, the lines of which diverged into the Mecoptera, Hymenoptera, and Coleoptera. Whilst these advances are eminently satisfactory, they contribute nothing to the solution of the two main problems of insect phylogeny—(1) the origin of insects as a class, (2) the origin of insect wings. It is to be hoped that

future discoveries will provide the clue to these fundamental questions

Chapters v and vi deal with the various sensory organs of insects, optic, olfactory, gustatory, tactile, and auditory, and end with an interesting discussion of the relationship of insect behaviour—chiefly reactions to chemical and photic stimuli—to applied entomology. Reflex behaviour is intimately associated with the functioning of sense receptors, which are either aggregated to form complex sense organs or diffusely distributed over the body as isolated sensillæ. Whilst the exact rôle of the latter is difficult to diagnose experimentally because of their minute size and heterogeneity, histological structure may occasionally suggest their correlation with determinate responses of the individual under specific stimulation. Both from the point of view of structure and experiment, it is not difficult to ascribe to the tympanal organs of insects an auditory function. In these, groups of sensillæ or scolopalæ are identified with a tympanum, all of which is strongly suggestive of an ear. In the scattered simple ligamentous chordotonal organs a definite tympanum is absent, but the scolopalæ are identical with those of tympanal organs. Eggers, who has studied the question meticulously, believes that the latter are 'rhythmometers', which co-ordinate and regulate intrinsic muscular movements. There is, however, no good reason why they should not also be considered as receptors of extrinsic vibrations in the surrounding medium, and they would thus be fundamentally similar to those chordotonal sensillæ that are combined to form definite organs.

The essentials of the theories of structural, pigmentary, and combination colours are excellently presented. The significance of coloration in the physiological processes of the individual tends, as the author remarks, to be relegated to the background. The subject of protective coloration has been widely discussed in entomological literature, and whilst the adherents of the theory of natural selection have invariably stressed, with no satisfactory proofs, the effect of the environment on the colour schemes of insects, they have entirely failed to realise that such a simple explanation is not readily tenable, since colour is the result of an intricate chain of chemico-physical processes within the organism.

Insect ecology and its practical application to the control of injurious species is assuming greater importance as time passes. It is generally recognised that the metabolism, behaviour, and distribution of insects are in great measure controlled by the

physical factors of the environment, and the principles that have been formulated as the result of experimental methods are of considerable significance in particular cases. A notable example is that of the Hessian fly, the attacks of which in North America have been in great measure circumvented by postponing the sowing of winter wheat in the autumn until the second generation of the fly has succumbed to the operation of natural lethal factors in the environment. In England, as a result of the information acquired through the experiments of Frew concerning the oviposition habits of the gout-fly, an important pest of barley, it was found that manurial treatment of the crop so alters the relative growth of stem and ear as to effect a reduction of the number of 'critical' leaves arising above the ear. The fly is thus forced to deposit the greater proportion of its eggs on the 'non-critical' leaves below the ear, with the result that the downwardly migrating maggots miss the vulnerable ear and finally succumb at the base of the ensheathing leaves of the stem.

The important phase theory of locusts advanced in 1921 by Uvarov, which appears to be amply supported by the evidence of recent field investigations, receives due notice. Whilst the theory does not pretend to explain the periodicity of locust outbreaks, it at least sheds light on the solitary and gregarious forms of these insects and their transition one to another. The value of the theory lies in the fact that the research worker is now provided with an instrument by means of which the whole problem of locust control may be thoroughly explored. All that is now required is the provision of financial aid sufficient to establish a competent international locust research organisation as Uvarov has advocated.

In order to deal adequately with the recent extensive research activities in parasitism and biological control, the author has found it necessary to devote the last hundred pages to their consideration. Ample attention is paid to the principles of host selection, the various expressions of parasitism, such as multi-, super-, hyper-, endo-, and ectoparasitism, the host relations of parasites, and the phenomenon of polyembryony in the Chalcidoidea, Proctotrypoidea and Vespoidea. The several aspects of biological control are fully discussed. Beginning with the introduction of *Vedalia cardinalis* into California to combat the cottony-cushion scale, the author then proceeds to describe the strenuous efforts to control the gipsy and brown-tail moths in New England, the mulberry scale in Italy, the levuana caterpillar in Fiji, and the larch sawfly in Canada, to mention but a few. Finally, due

consideration is given to the factors governing parasitic introductions, the utilisation of indigenous parasites, and the biological control of noxious weeds

It only remains to say that typographical errors are few, that the illustrations, of which there are eighty-four, have been well chosen, and that there is both a general and an authors' index. The ample bibliographies at the end of each chapter will serve as a useful guide to the sources of further information

A. E. CAMERON

### An Encyclopædia of Scientific Agriculture

*Baillière's Encyclopædia of Scientific Agriculture*  
 Edited by Dr Herbert Hunter. In 2 volumes  
 Vol 1 A-L Pp xvi+675+plates 1-17 Vol  
 2 M-Z Pp 677-1361+plates 18-29 (London  
 Baillière, Tindall and Cox, 1931) 63s net

**A**BSTRACTING journals and periodic reviews of progress, by which the pure sciences meet the difficulty of the rapid growth of their literature, leave certain needs in agricultural science unsatisfied. In their applications to farming practice the various sciences become closely interdependent and, also, the scientific worker in agriculture must watch closely the alterations and advances in practical husbandry. Further, the practitioner, with science bearing ever more forcibly upon his activities, stands in need of a specially prepared presentation of its applications to his industry. An encyclopædia of scientific agriculture is thus a logical and timely enterprise in which the investigator, the teacher, the student, and the farmer are certain to be interested.

In forming a first judgment of an encyclopædia, one must be guided largely by the ideas upon which the work is based. The principle adopted has been to present the various branches of agriculture in the forms they have assumed under the influence of science. An acquaintance with the chief customary operations and the equipment of husbandry on the part of the reader has been assumed. With these ideas in mind there has been enlisted the help of an unquestionably authoritative body of contributors, nearly ninety in number. Supplementing the original articles of the contributors is a considerable body of descriptive matter arranged, like the articles themselves, alphabetically. Choice and composition of this descriptive matter must have been very difficult. Whether in some cases the editor may not have been too indulgent may perhaps be questioned, but it is certain that his selection will prove helpful to all the types of reader he has endeavoured to serve.

A very wide range is covered by the original articles, but certain important branches of agriculture have, by design, been excluded. Livestock is the most important of these, the reason being, here, that the breeds, management, etc., have a full, up-to-date literature of their own. Poultry, however, relatively new to commercial farming in Great Britain, is covered in all its aspects by excellent articles. To exclude animal diseases was inevitable, for a popular account would not have been in keeping with the purpose of the "Encyclopædia", while descriptions of recent advances and current problems would have unduly strained its scope. It is, perhaps, to be regretted that the important applications of physical chemistry to fungicide and spray materials has found no place.

In their writings on the soil, crop varieties, animal nutrition, fruit and vegetable crops, storage, and marketing, the contributors have assembled new knowledge for which any but the specialist would formerly have had to search through a very scattered field of publications. In not a few cases, the original articles, in addition to their value in building up the "Encyclopædia", are distinct and welcome contributions to the literature of their subject. Certain fields have been covered in which no precise applications to practice have yet emerged but in which knowledge has made important recent advances. Drought resistance and the influence of low temperatures upon plant growth are among these special cases, the inclusion of which is a great asset to the work.

Room is found for some subjects not directly suggested by the title of the "Encyclopædia". Thus certain legal enactments are included for the sound reason that these are based upon chemical or other scientific evidence. There is, too, a series of articles describing the agriculture of the British Dominions and of some of the Colonies. The importance of these stands out clearly in the light of recent research and, even more, of the present economic situation.

The merits of an encyclopædia, whether as to choice of matter or arrangement, can be gauged only by using it for reference in normal fashion over a considerable time. But a first inspection leads to the belief that the many interests comprised by the broad field of agriculture and its sciences will find in the "Encyclopædia of Scientific Agriculture" a ready and dependable source of help. The publishers are to be commended for the nature and magnitude of their enterprise and congratulated upon the hands to which they entrusted it.

## Short Reviews.

*The Journal of the Institute of Metals* Vol 46  
 Edited by G Shaw Scott Pp xii + 571 + 47  
 plates (London Institute of Metals, 1931)  
 31s 6d net

THE high reputation of the *Journal of the Institute of Metals* is worthily maintained by the latest issue. Commencing with the Autumn Lecture on "Thin Films in Relation to Corrosion Problems", by U R Evans, several subsequent papers deal with allied questions. The increasing use of the spectroscope in industry is shown by two contributions on this subject, which, together with the discussion upon them, represent substantial addition to our knowledge in this direction. Two further papers, both by Prof Hanson and Mr Slater, deal with the causes and the elimination of unsoundness in sand castings of aluminium. The profound influence of water vapour in the furnace atmospheres is most clearly demonstrated, and the importance of the conditions under which the metal is stored between the time it is first produced and that at which it is cast is emphasised. Three papers deal with the subject of the drawing of wire: two with the nature of the flow and the factors which affect it, the third with the changes of tensile strength of high conductivity copper as it is drawn down.

One of the most outstanding features of this volume is the remarkably wide range of the researches published, and few who are interested either in general metallurgy, or in specific metallurgical processes, can fail to find much of direct interest. In addition to the topics already mentioned, others dealt with include the production of copper-nickel alloys of high elastic limit, the application of electric furnaces to the manufacture and working up of the non-ferrous metals, the effects of cold-rolling and heat-treatment on alloys of lead, the ageing of duralumin, etc. The proportion of papers of practical importance is unusually high, but the purely metallographic aspects of the Institute's interests are equally well represented. If one of such papers may be selected, attention may be directed to that of J A Murphy on the silver-mercury diagram, which is of more than usual difficulty and merit. F C T

*Social Behaviour in Insects* By Dr A D Imms  
 (Methuen's Monographs on Biological Subjects)  
 Pp ix + 117 (London Methuen and Co, Ltd,  
 1931) 3s 6d net

A SOCIAL system, existing in small winged or wingless insects, long before man had evolved, having its *raison d'être* in instinct and physiology rather than intelligence, yet possessing remarkable similarities to the system which man built round himself! What more fascinating study could one find in the realm of Nature than that of these six-legged creatures. Like us, they care for their young, nursing them in cradles and feeding them on the most appropriate food. They may keep armies for defence or aggression, or may turn to the

peaceful pursuits of the dairy-farmer and husbandman. They even have sufficient sense of property to leave real estate to their offspring.

In this little book, Dr Imms sets out to explain the behaviour of social insects, the basis of this behaviour in morphology, and the paths which they may be supposed to have traversed in evolution. The big majority of insects are solitary creatures, independent of each other, except for reproductive purposes. They die soon after oviposition and therefore have little opportunity to become interested in their offspring.

A striking clue to the evolution of communal life in these animals is to be found in sub-social forms where the family system is in process of establishment. Here we learn of the great significance which attaches itself to reciprocal feeding between adult and young forms, to the exploitation of flowers, and the dependence, total or partial, of caste formation and its associated polymorphism, on nutrition. How far the condition presented to us—of a vast proletariat of sterile working classes, each individual merged into the community, to which it may at any time be mercilessly sacrificed—is one to be emulated or not, the reader may decide. Many will agree with the author and "take comfort that a system of this kind is unattainable by repressive manifestations on the part of the most ruthless human dictatorship."

*Forest Life and Adventures in the Malay Archipelago.*

By Dr Eric Mjöberg. Translated from the Swedish by A Barwell. Pp 201 + 84 plates  
 (London George Allen and Unwin, Ltd, 1930)  
 12s 6d net

ANYONE desirous of prosecuting a biological research expedition to the tropics would be well advised to read this little book, which is charmingly written and illustrated, and equally well translated. In the thirty-one chapters, "each complete in itself and requiring no further index", we read of such giants of the forest as the elephant, the rhinoceros, and the buffalo, delighting as much in the habits of them as in the exciting incidents of the hunt. The goat-antelope, living in impenetrable tracts round volcano summits and only seen once before by a white man, is described and pictured to us. We are told that though it is two-horned, it is to this animal that we must refer the mythical unicorn. Another interesting mammal is the scaly, hairless ant-eater or pangolin, which simulates death amid myriads of ants. When in their hunger and curiosity enough ants have entered beneath the scales, the pangolin shuts these down and calmly enters the nearest pool. The ants, on release, rise to the surface of the water, from whence they are skimmed by means of his sticky tongue.

Space is not available to do more than mention here such marvels of Nature as the flying frog, poisonous fish, fish which walk on land, the trilobite larva, 2½ inches long—neotenic females whose mates are insignificant blue-black beetles no longer than one-fifth of an inch. To the author belongs the honour of having solved this century-old enigma.

Mjöberg is as interested in the Malayan native

as he is in the flora and fauna, and it is to the friendships which he struck with these people, who are still as likely to collect human heads as camphor, that he owes much of his information

*Die Tierwelt der Nord- und Ostsee* Begründet von G Grimpe und E Wagler Herausgegeben von G Grimpe Lieferung 18 Teil 10a *Phyllopoda*, von Walther Rammner, Teil 10e<sub>2</sub> *Isopoda genuina*, von H F Nierstrasz und J H Schuurmans Stekhoven, Jr, Teil 10e<sub>3</sub> *Anisopoda*, von H F Nierstrasz und J H Schuurmans Stekhoven, Jr, Teil 10e<sub>4</sub> *Isopoda*, Nachtrage und Berichtigungen, Inhaltsübersicht Pp 32+77+34+5 (Leipzig Akademische Verlagsgesellschaft m b H, 1930) 13 50 gold marks

THE present section containing the Phyllopoda and the Isopoda is a most useful addition to this series of short monographs on the various groups in the fauna of the North Sea and Baltic. There are few Cladocera in the area covered. *Podon* and *Eradne* are the only truly marine genera, *Bosmina coregoni maritima* being a variety of a freshwater species which is capable of living in the low salinity of the Baltic. The general account of these is full and well illustrated. The remainder of the section, and by far the greater portion, is taken up with the Isopoda, divided into *Isopoda genuina* and *Anisopoda*. Here we have abundant material in both divisions. In the first part, after very brief notes on anatomy and biology, with a table of distribution of all the species to be found in the Baltic and North Sea (81 in all), the account is a systematic one. This is extremely useful, for, with the exception of Sars' "Isopoda" in "An Account of the Crustacea of Norway", there is no work which describes and figures all the species in detail. Nearly all the illustrations are actually taken from Sars' own figures and are excellent. Parasitic species, of which there are many, are also included. The section on *Anisopoda* is on the same lines and equally well illustrated.

*Nature in the Garden Wild Life at our Doors* By Edward Step In 2 volumes (The "Come-with-Me" Books) *Early Days to Early Summer* Pp x+149+31 plates *Midsummer to Winter* Pp x+149+31 plates (London and New York: Frederick Warne and Co, Ltd, 1931) 2s 6d net each vol

IT is a pleasure to pick up a work such as the late Mr Edward Step has given us in his "Nature in the Garden". The irresistibly charming intimacy with which the author treats his subject by taking his readers on a Nature ramble around any typical English garden, whether in the town or country, will induce many to indulge in a pleasurable study of these two volumes. It is surprising what a vast amount of fact and helpful knowledge has been packed into these two small books, and after reading them through it is difficult to conceive of anyone failing to feel a greater interest in the natural history of his garden.

The numerous plates and illustrations are a great asset and show care taken over detail, besides being

helpful and instructive to the reader. Without hesitation we may say that this work entirely fulfils the intention of the author, namely, to explain in simple non-technical language a few of the more obvious natural forms that appear in almost every garden. An added interest lies in the assurance given by the author that all the creatures mentioned in the pages of his two volumes were actually found by him in one or other of the gardens which he had owned from time to time.

*Jungle Ways* By Wilham B Seabrook Pp 316 (32 plates) (London, Bombay and Sydney: George G Harrap and Co, Ltd, 1931) 10s 6d net

MR SEABROOK, as he has shown in his previous writings, is keenly interested in all manifestations of magic and the occult. His visit to Africa, in fact, was largely inspired by a desire to study African magic in its native home as a result of his experience of voodoo in Hayti. His journey in French West Africa fell into four stages. He began in the Ivory Coast area among the Yafouba, an excellent district for the study of magic. He then went on to the Gueré cannibals. An interlude at Timbuctoo was followed by a visit to the Habbé cliff-dwellers. When the author was with the Yafouba he was taken under the wing of a young witch and with her assistance had an excellent opportunity of observing the working of magic in everyday life. He also witnessed a remarkable exhibition of the impaling of young girls on swords. He is no more able to offer an explanation than others who have seen similar performances elsewhere. Among the Gueré he experimented in cannibalism, and describes in some detail the appearance and preparation of the dish and his sensations before, during, and after. In the last section of the book are some striking pictures of phallic rites. The merit of the book lies in its vivid descriptions rather than in its additions to scientific knowledge.

*Field Book of Ponds and Streams an Introduction to the Life of Fresh Water* By Prof Ann Haven Morgan (Putnam's Nature Field Books) Pp xvi+448+23 plates (New York and London: G P Putnam's Sons, 1930) 15s net

A USEFUL book, well qualified to meet the needs of the naturalist anxious to learn about the many members of the flora and fauna of fresh waters. It cannot be expected that such a work could always guide to specific determinations, but often it does so, and the illustrations and descriptions of habits are so definitely to the point that the honest student may attain generic accuracy. Two chapters on varieties of habitat and methods of preserving water animals make an excellent introduction. Unfortunately for us, the book is concerned with American forms of life, and although fresh-water faunas bear a great resemblance the world over, there are groups, especially the vertebrate groups, which scarcely apply to Great Britain. A similar compact ecological treatment of our own fresh-water faunas would be a boon to students on this side of the Atlantic.

## Petroleum in Australia

SO much has been heard in the past concerning the prospects of commercial oil supply from indigenous resources of the Commonwealth, that mere mention of the subject is inclined to call forth expressions of scepticism and recollections of past disappointments. But whatever opinion may prevail in technical or financial circles at the moment, perusal of Dr W G Woolnough's report of his tour of inspection of the oilfields of America and Argentina, as bearing on prospects in Australia,\* is certainly worth while, if it does not convince in its object, it at least provides a most readable account of the industry in the first two countries, and a very fearless statement of the facts as regards Australia.

The dictum that "nobody but an optimist ever discovered oil" may be taken as the key-word of this report. Dr Woolnough is clearly an optimist, but his is an optimism based on sober statement of facts, not on extravagant claims. He has toured the Americas widely and has learnt much, as everyone does who makes a similar journey, from the generous insight into the industry which is accorded the visitor. There is scarcely a single phase of the industry which is not discussed or referred to in its bearing on modern practice and tendencies throughout the oil centres of the world, and the author of this report is equally loud in his condemnation of the unsound as he is in praise of the activities which have made the American petroleum industry what it is to-day.

What seems to be needed in Australia, *pace* past efforts and all that has been written on the subject, is first of all a totally different attitude on the part of the public as a whole towards the actual prospect of finding oil. As in recurrent instances in the history of the American industry, the word petroleum has too often been interpreted in terms of stock-market activities, exploration should be unaccompanied by gambling in shares of companies, the claim of which to assets may only lie in mineral rights or prospecting rights. Exploration for oil needs money (seldom contributed from share funds), patience, up-to-date technique, and first-class initial research. Dr Woolnough shows that Australians have a great deal to learn in the way of setting about to establish the claim that oil does indeed exist in the continent, and he is clearly impressed with the lessons that can be learnt from American operators.

In some respects it is a pity that this report has come at a time when the financial resources of the country are strained, and when economic conditions generally are against further bold enterprise to probe the question of oil prospects. While the competent geologist, weighing up his claims, may not agree with many of Dr Woolnough's opinions in a broad way, there is no doubting the sincerity of purpose underlying his estimate of possibilities,

and it would be a thousand pities if, because the moment is inopportune, his work were to be shelved and possibly forgotten. His arguments are interesting. The widespread belief that Australia is geologically too old to contain petroleum, he regards as fallacious. Equally valueless—and here we are at one with him—are the ideas that oil cannot occur commercially south of the equator, other than in tropical regions, and that "there has been a special dispensation of Providence in favour of the United States" in the matter of petroleum supplies. Again, indifferently qualified (and often incompetent) oil men drift from America into Australia, set themselves up as 'experts', from whom come some of the inaccurately worded prospectuses which have in the past misled the public. This sort of thing is checked to some extent in America by protective legislation, it should be similarly checked in the Commonwealth.

Paying tribute to the good work done in Australia in connexion with oil exploration in the past, Dr Woolnough states quite unequivocally that nowhere does that work approximate in detail or completeness with the ordinary routine in the American oilfields. This is probably correct, but it must be borne in mind that had a really substantial oilfield been discovered in Australia, even by the 'blind stabbing' methods of the old days in the United States, such routine efficiency would have come about automatically, and comparisons would not to-day have been so unfavourable between the methods of the two countries. For what has been wanted, quite apart from a change of attitude of Government and people, has been the actual finding of a good field. In other words, the encouragement which achievement gives. Had there been a really lucky find in the past—the discovery of an oilfield of commercial magnitude comparable with any one of the unit-producing oilfields of the States during the last twenty years—the whole trend of the search for oil in the island continent would have been altered.

Another sidelight on Australian conditions may be quoted verbatim. "It cannot be too strongly insisted that absolute freedom of entry to responsible geologists makes for the most rapid and most economical development of potential oil resources, and that such entry in no way prejudices the interests of the holders of the land. The Australian system of taking up blocks of land without previous survey, and often by the process of marking them off on a map without even visiting the area, would be ludicrous were the effects less tragic." We doubt whether the annals of metalliferous mining history in the continent, wild incidents though they show, can point to more painful examples of that 'get-rich-quick' psychology which has proved so detrimental to sound oil exploration in the past.

Then there is the question of adequacy of geological maps. It is not sufficiently widely understood that in order to get the maximum amount of information of geological circumstances, thus

\* The Parliament of the Commonwealth of Australia. "Report on Tour of Inspection of the Oil-Fields of the United States of America and Argentina, and on Oil Prospects in Australia." By Dr W G Woolnough. Pp 118. (Canberra: H J Green, 1931.) 5s.

to lessen cost of drilling in places foredoomed to failure, months (not days) of careful mapping are necessary. The author rightly enjoins his countrymen that there can be no "really wholesome appreciation of the seriousness of oil search" until such ideas are abandoned.

Thus it all comes down to the fact that prospects are still good, given active, honest, and modern methods. The introduction of overseas capital and technique, under proper and stringent safeguards, is urged. Petroleum will not be won by the 'gold-rush' principle, even if it exists in sufficient quantity to justify the optimism of this

report, but at the same time it seems probable that unless the Government takes another hand in securing unfettered and co-ordinated research for oil in those parts of the continent where the Survey officers consider the most favourable chances to lie, then private enterprise will have to receive a considerable 'boost', either in the form of new financial resources or tempting technical information, before it will move. But when it comes, whether from national or individual impetus, the problem of oil in Australia will at least have been clarified in its main ethical and technical aspects by the publication of this excellent essay.

### Infantile Anæmia and Diet.

THE appearance of a new disease always excites comment, but the disappearance of a common malady may pass without notice. Up to about twenty years ago, a type of simple anæmia, styled 'chlorosis', was prevalent among young employed women in Great Britain. It was easily cured by the administration of iron. To-day, with the improvement in the standard of life of working women, the disease appears to have vanished. Recent investigations have shown, however, that a similar type of anæmia occurs amongst infants, which also can be cured by adding iron to the diet.\* The anæmia is of the so-called 'simple' or 'chlorotic' type, it is characterised by a marked reduction in the hæmoglobin percentage of the blood, without other changes.

The newborn infant is provided with a store of iron in its liver, about two-thirds of that present in the body at birth is laid down during the last three months of intra-uterine life. Thus the premature infant is born with only a small store, although the amount of iron per kilogram body weight is not much less than that found in the full-term baby. After birth the iron store is drawn upon so that by about six months of age it is no greater than in the adult liver. Milk contains little iron, cow's milk less than human. The chief sources in a diet are meat, eggs, and some green vegetables. Examination of the iron stores of newborn animals of different species has led to the conclusion that when an animal is dependent in its early life upon its mother's milk, the iron required for the formation of the hæmoglobin of its blood is supplied from a store in the liver which is laid down during the later stages of intra-uterine life, while when it is capable of fending for itself soon after birth such a store is unnecessary and is not found. The mammalian organism finds it easier to transfer iron from the mother to the child via the placenta than via the mammary glands and the milk.

A nutritional anæmia can be produced in young animals by an exclusive diet of milk, especially if the parents have been maintained on a diet deficient in iron. In the rat, this anæmia can be cured by

the administration daily of small doses of iron together with copper. This observation, which appears well substantiated, may explain the contradictory results which have been reported in the treatment of experimental and infantile anæmias by administration of iron salts. This type of anæmia is not due to a vitamin deficiency, nor is it influenced by light treatment.

Dr Mackay has examined during the past five years 1090 infants and 168 expectant and nursing mothers. The number of hæmoglobin estimations was 4811 on the infants and 315 on the mothers. Part of this work has already been published; the present report refers especially to 174 artificially fed and 230 breastfed infants and 83 mothers. The economic status of the parents of the breastfed babies was slightly better than that of the artificially fed. The fathers were usually small traders or manual workers. The infants were attending the Infant Welfare Department of the Mothers' Hospital of the Salvation Army or the Outpatient Department of the Queen's Hospital for Children. Their ages ranged from 2½ weeks to 13 months. The artificially fed children were given dried milk with a cane sugar addition, and cod-liver oil and orange juice, up to 8 months of age. The breastfed were also given cod-liver oil and orange juice. Weaning began at about 8 months; thereafter a mixed diet was given to both groups. When iron was given to the artificially fed infants it was supplied as iron and ammonium citrate in the dried milk used ("Hemolac"), 31½ grains being added to each pound of milk, so that an infant consuming 1 lb. of milk in the week received 4½ grains of the salt daily. The iron salt used contained a trace of copper, and the dried milk also contained traces of copper and manganese. When mixed feeding was instituted the amount of iron and copper in the diet was considerably increased, since most foodstuffs are richer in these elements than milk. The hæmoglobin estimations were made by Haldane's method, the blood being obtained from a prick on the heel.

The hæmoglobin percentage of the untreated, artificially fed infants showed a sharp drop in the first month of life from the high birth value to about sixty-five per cent at 2-3 months old, a subsequent steady rise to 70 per cent at 5-6 months, and then a continuous drop to 65 per cent at 12

\* Medical Research Council Special Report Series, No. 157. Nutritional Anæmia in Infancy with Special Reference to Iron Deficiency. By Helen M. M. Mackay, assisted by Lorel Goodfellow, with a Statistical Appendix by A. Bradford Hill. (London: H. M. Stationery Office, 1931.) 2s net.

months old. The hæmoglobin curve for the breast-fed babies was similar, though running at a slightly higher level. Iron treatment of the artificially fed infants raised the hæmoglobin level from 3 months of age to about 80 per cent. Other very important observations were that iron treatment approximately halved the morbidity rate, both for diseases of the respiratory and of the gastrointestinal tract, as well as improving the rate of growth. The relatively low hæmoglobin level of the breastfed infants was not due to bacterial infections or nutritional upsets.

The hæmoglobin percentage of the mothers was 75-80, that is, somewhat below the standard for women. The administration of 10-30 grains of iron and ammonium citrate daily before confinement for one to two months had no significant effect upon the hæmoglobin level, when treatment was continued for 6 months after the birth of the infant the hæmoglobin rose about 10 per cent, as compared with a rise of 5 per cent in untreated mothers. The tendency to recovery from anæmia is thus aided by giving iron. No evidence was obtained that this treatment influenced the anæmia of the infants, but it is possible that a longer ante-natal administration might have a favourable effect. Some evidence was obtained that physical immaturity and anæmia in the mother predisposed to anæmia in the child.

Further analysis of the data showed that the greater the rate of growth after birth the more likely was anæmia to develop; babies of small birth weight grow more rapidly than those which are

larger at birth, and anæmia becomes very evident about 6 months of age. The lower the birth weight also the greater is the average drop in the hæmoglobin level within the first 3 months of life. Slight infections do not appear to influence the hæmoglobin, but any severe illness which causes anæmia will hasten the onset of iron deficiency, so that iron treatment is required in the convalescence from such infections.

From the results of this research it is possible to deduce the normal hæmoglobin level in infancy as contrasted with the average level. For the first 3 months the average of the breastfed infants is considered to be the normal, thereafter that of the artificially fed babies supplied with iron. From the curve thus constructed it appears that the hæmoglobin percentage sinks from about 100 at birth to 70 at 2-3 months of age and thereafter rises to 80, this level being reached a couple of months later and being maintained until the end of the first year of life. On this standard about forty-five per cent of breastfed and fifty to seventy per cent of artificially fed infants have a hæmoglobin level ten per cent or more below the normal. The important conclusion reached is therefore that all artificially fed and many breastfed babies should be treated prophylactically with iron for the former a medicated milk is convenient, for the latter a solution of the iron salt in water suitably flavoured can be used. By this means anæmia will be prevented and the incidence of infections will be greatly reduced.

### John Mayow's Place in Chemistry.

AN interesting paper by Prof T S Patterson, entitled "John Mayow in Contemporary Setting: a Contribution to the History of Respiration and Combustion", appears in vol 15 of *Isis* (Feb-Sept 1931). In the course of a comprehensive and fully documented article of 93 pp, Prof Patterson describes the results of a detailed examination of Mayow's "Tractatus duo" (1668) and "Tractatus quinque" (1674), and of contemporary works by Boyle, Hooke, Willis, Lower, Swammerdam, and other authoritative writers of the period upon the subjects of respiration and combustion.

It is evident from the character of this scholarly publication that the author has spared no effort to acclimatise himself in the scientific atmosphere of the Restoration period, so much so, that anyone who reads his critical appraisal of Mayow's work must receive his considered judgment with respect. This is to the effect that modern writers, mainly owing to their failure to go back to original sources, have (1) greatly exaggerated the resemblance of Mayow's views to our own, (2) read into his statements ideas that were not in his mind, (3) credited him with the discoveries and views of others, (4) confused his two works, (5) depended upon what has been written about him, rather than upon what he wrote. "An astonishing piece of special pleading" put forward by

Yeats in 1798 is held responsible for most of the later exaggerations, and among the more recent writers who are quoted as having espoused the cause of Mayow with an unjustifiable enthusiasm are Rodwell (1874), Ramsay (1896), Gotch (1908), Gunther (1921), Singer (1928), Haldane (1929), and Dampier-Whetham (1929).

Thus, in Prof Patterson's judgment, Mayow's "De Respiratione" is a succinct and fairly clear summary of views that had already been published by others, and in other parts of his treatises it is scarcely too much to say that the things that were true were not new, and vice versa. The following reference by Prof Patterson to a passage from a modern historical work may be quoted as a typical criticism based upon his preceding analytical exposition of Mayow's writings.

"In practically every detail this description is entirely erroneous—at least, if we are to understand that everything here attributed to Mayow is to be regarded as having been actually discovered by him—otherwise it has little or no meaning. Mayow was not the *first* to show that a candle enclosed in a flask goes out while there is still, apparently, abundance of air, he was not the *first* to infer that air is heterogeneous, he was not the *first* to suggest the existence in air of a vital substance also to be found in nitre and nitric acid, he was not the *first* to call this substance nitro-

aerial spirit, he was by no means the *first* to show that gunpowder can burn without the assistance of air, he was not the *first* to prove—if he made the experiment at all—that the calx of a metal was heavier than the metal, he was not the *first* to show that an animal placed in a closed vessel died more quickly if a lighted candle was also placed in the vessel. It was not Mayow who *first* suggested that animals exhaust the air of some constituent necessary to life which enters the blood in breathing, and he was not the *first* to infer that this part of the air was the nitro-aerial spirit. And if he was not the first to show or suggest these things, why should he be credited with them? Moreover, he said nothing about combustion in 1669. The only statement which is *partially* correct is that Mayow attributed the increase of weight on calcination of antimony—he did not extend the suggestion to other metals—to combination with igneo-aerial particles, but, as has been shown above, this was merely the adoption of a notion already published by Boyle, and, in addition, since Mayow's idea of

nitro-aerial spirit was very different indeed from our notion of oxygen, it could lead neither Mayow nor his contemporaries any way towards a comprehension of combustion and respiration. Therefore it was ignored, and quite rightly so. Mayow's so-called 'discovery of oxygen' was not forgotten, it was never made."

Prof Patterson has done yeoman service to a cause he has at heart, by undertaking this laborious investigation with such painstaking care. His judgments are severe, but his argued conclusions are bound to impress his readers and help to reshape their conceptions of an important scientific epoch. The appearance of this critical study, long overdue, of Mayow's position among his contemporaries will therefore be welcomed by all students of historical chemistry. A serious study of original sources in this field is not free from drudgery, but we may hope that Prof Patterson's provocative foray into the pre-phlogiston era will induce other chemical historians to burnish their weapons and take the field with (or possibly against) him. JOHN READ

### Obituary.

SIR ALFRED YARROW, BT, FRS

WE much regret to announce the death, which occurred on Jan 24, of Sir Alfred Fernandez Yarrow, the veteran marine engineer and shipbuilder. The son of a clerk in the employ of a West India merchant in the City of London, Sir Alfred Yarrow was born on Jan 13, 1842. Evincing from his earliest years great natural ability, Yarrow attended first a small private school, and then at the age of thirteen years entered University College School, where he had Joseph Chamberlain as a schoolfellow. At the age of fifteen and a half years he was apprenticed to Miller, Ravenhill, and Salkeld, an eminent firm of marine engineers on the Thames, which had been founded by Joseph Miller in 1822 and had gained a high reputation as makers of machinery for mercantile vessels and for warships. One of the contracts completed by the firm during Yarrow's apprenticeship was the machinery for the cross-Channel steamer *s.s. Leinster*, one of four very notable craft running between Holyhead and Dublin, having a speed of eighteen knots.

On the completion of his apprenticeship, Yarrow, having with his friend Hilditch invented a steam plough, became connected with a firm of engineers of Chelmsford, and while acting as their London agent he was able in the course of two or three years to save £1000. Then in 1866, with a partner named Hedley, he set up as a builder of steam boats in a small yard on the eastern side of the Isle of Dogs, close to the Folly Inn, where it is said Charles II. used to pay clandestine visits to Nell Gwynne.

The Thames at this time was the centre of a flourishing shipbuilding industry. Below Yarrow's premises were the yards of Wigram and Green, with a history dating back to the time of Elizabeth, and the famous Thames Iron Works, while above were the establishments of Samuda, Dudgeon and Westwood, and Bailhe, the last of which was taken over by Yarrow in the 'nineties and thus became

the birthplace of some of our early torpedo boat destroyers. Though their first balance-sheets were not satisfactory, the tide of fortune soon turned in favour of Yarrow and his partner, and in the period 1868-75 they turned out no fewer than thirty-five steam boats. In 1875, Yarrow became the sole owner of the concern.

Just as the demand for fast sea-going vessels during the American Civil War had been a boon to the shipbuilders of the 'sixties, so the coming of the torpedo gave Yarrow and his rival, Sir John Thornycroft, whose works were higher up the river at Chiswick, their great opportunity. Beginning in 1873, Yarrow devoted himself to the design of fast steam boats for carrying torpedoes, and at a review at Spithead in 1878 two of his boats, uninvited, accompanied the Queen's yacht from Portsmouth. Though nominally a breach of etiquette, the performance of the boats led the Queen to say they had interested her more than anything else at the review. Six days later the Prince of Wales, afterwards King Edward VII, took a trip in one of them, and it was also one of Yarrow's boats that the present King commanded in 1889.

Though Yarrow's work was not confined to torpedo boats and torpedo boat destroyers, it was with these he achieved his greatest successes. The results of his work, like that of his eminent contemporaries, Thornycroft and Augustin Normand, of Havre, are written in the history of our modern navies. Fast-running reciprocating steam engines, forced draught for boilers, the well-known Yarrow water-tube boiler, superheating, balancing, the use of high tensile steel, and other matters all engaged his attention, and many of his vessels, such as H.M.S. *Hornet* and the Russian destroyer *Sokol*, created remarkable records. The *Sokol* was the first vessel in the world to steam at a speed of thirty knots. In the fifty years, 1868-1918, Yarrow turned out an aggregate of 127,000 tons and a total of 1,700,000 horse power, while his vessels placed end-

to-end would stretch a distance of thirteen and a half miles

Economic factors having made shipbuilding on the Thames unremunerative, Yarrow in 1906 transferred his works to Scotstoun on the Clyde, and it was there that the famous river gunboats for the Tigris campaign were launched

Of Yarrow's public work and his benefactions to the nation it is difficult to speak too highly. A member of the council of the Institution of Naval Architects from 1887, he contributed several papers to its *Transactions* and was always ready to place his valuable experience at the service of others. In 1894 he founded the Yarrow Convalescent Home for Children at Broadstairs. Some years later, at a cost of £20,000, he presented the country with the experimental tank at the National Physical Laboratory at Teddington. He was elected a fellow of the Royal Society in 1922, and in 1923, to mark his sense of the value of research, he made a gift to the Society of a sum of £100,000. In a letter accompanying the donation, Sir Alfred stressed "that the money be used to aid scientific workers by adequate payment and by the supply of apparatus or other facilities, rather than to erect costly buildings". Sir Charles Sherrington's presidential address to the Royal Society that year was devoted mainly to an account of the steps which had been taken to make the fullest use of this and other sums in hand for the benefit of research. It was decided to institute research professorships, to be awarded to workers of proved ability for independent research, and mobile both as regards the university at which they can be held and also as to subject of research. Prof. A. Fowler, professor of astrophysics in the Imperial College of Science, and Mr. G. I. Taylor, fellow and lecturer in mathematics in Trinity College, Cambridge, were appointed to Yarrow research professorships forthwith, and Prof. O. W. Richardson, professor of physics at King's College, London, in the following year. In 1926, Sir Alfred again placed scientific workers deeply in his debt by a gift of £10,000 to the British Association, to be used for general purposes, with the stipulation that it was to be expended, as to both capital and interest, within a period of twenty years. He believed that the present needs of the Association, in its work for science, should receive precedence over provision for the distant future.

With the passing of Sir Alfred Yarrow, the world has lost a great leader of industry, a pioneer of marine engineering science, and a generous benefactor of the cause of scientific study and research.

#### DAME BERTHA NEWALL (née PHILLPOTTS), D B E

WE regret to record the death of Bertha Surtees Newall, more widely known under her maiden name of Phillpotts, which took place at Cambridge on Jan. 21, at the age of fifty-four years. Miss Phillpotts was the daughter of James Surtees Phillpotts, for many years headmaster of Bedford Grammar School. She entered Girton as a student, and took first-class honours in the Medieval and Modern Languages Tripos in 1901. In addition to

the course laid down for her schools, she took up with enthusiasm the study of the Scandinavian languages under Mr. Eiríkr Magnússon. Her College appointed her Pfeiffer student and College librarian, but she resigned in 1910 to study archaeology, acting as secretary to the late Baron A. von Hugel. In 1913 she published her first book, "Kindred and Clan", and was appointed the first holder of the Lady Carlisle fellowship at Somerville College, Oxford. During the War she served as private secretary to the British Minister at Stockholm, perfecting her knowledge of Scandinavian languages and visiting Iceland six times. In 1919 she returned to take up an appointment at Westfield College in the University of London. Here she published her second and best-known book, "The Elder Edda and the Ancient Scandinavian Drama", of which the merit was immediately recognised.

In 1922, Miss Phillpotts became Mistress of Girton College, doing much valuable administrative and organising work for the College, and sitting as the only woman member on the Statutory Commission for the University of Cambridge. The strain of the work and private anxieties led to her resignation, and once more she became a student resident in Cambridge. In 1926 a generous donation of £10,000 from Sweden led to the institution of a School of Scandinavian Studies in the University, for the organisation of which Miss Phillpotts was largely responsible, and of which she was appointed director.

Miss Phillpotts had been made an O B E in 1919, and was promoted to D B E in 1929. She was Litt. D. of the University of Dublin. In 1931 she married Prof. H. F. Newall, professor of astrophysics in the University of Cambridge, 1909-1928.

Miss Phillpotts' published work, scholarly and erudite as it is, scarcely affords a true index of her commanding position in the field of studies she had made her own. Her profound knowledge of the languages, ancient literature, and antiquities of Scandinavia was fully recognised in the north of Europe, where she was regarded as one of the very few outstanding authorities on these subjects.

REFERRING to the death of Prof. E. S. King, on Sept. 10, which was announced in *NATURE* of Nov. 21, Dr. Harlow Shapley, director of the Harvard College Observatory, writes: "Prof. King was astronomer for more than forty years at the Harvard College Observatory. For many years he had been in charge of the photographic work, and had been important therefore in building up the great collection of astrophotographic plates. His own researches were largely in various fields of photometry, and his standards of stellar colour index have been internationally used for many years. In his researches on the colours of the brighter stars he directed attention to the probability that the solar system lies within a thin, nebulous envelope, perhaps only a few hundred light years in diameter, and thus he was the pioneer among the investigators who find the absorption of light in space localised in the local system."

## News and Views.

## Bicentenary of Gabriel Jars.

On Jan. 26 occurred the bicentenary of the birth of the eminent French mineralogist and civil engineer, Gabriel Jars, the author of "*Voyages métallurgiques*", which at the time of its publication was a cyclopædia of information on mining in Europe in the middle of the eighteenth century. The son of a miner, Jars was born at Lyons and became one of the earliest students of the *École des Ponts et Chaussées*, which had been founded in 1747 for the training of engineers for the Government service. Having gained both practical and theoretical knowledge of the art of mining, he was sent in 1757 with Duhamel du Monceau to visit the mines of Europe, with the view of the introduction of improvements into the mines of France. His first tour took him through the central countries of Europe, but afterwards he visited England and Scotland, and the Netherlands and Scandinavia. In 1768 he was admitted a member of the Paris Academy of Sciences, and he was arranging the accounts of his journeys when he suddenly died of sunstroke. His death took place at Clermont on Aug. 20, 1769, when he was only thirty-seven years of age. His brother had accompanied him on his later journeys, and to him fell the task of publishing the "*Voyages métallurgiques*", which appeared in three volumes during the years 1774-81.

## Working-Class Conditions in Bombay

A SOMEWHAT lurid light is thrown upon the effect of industrialism and its attendant conditions on the 'working classes' of Bombay by an analysis of certain statistics published by Dr G. S. Ghurye and S. R. Deshpande in the *Indian Journal of Economics* for October. The statistics were collected by the Bombay Labour Office in co-operation with the Young Women's Christian Association with reference to infant mortality. The number of individuals from whom the particulars were compiled was 2053. The subjects of the inquiry were mainly of agricultural class origin, and mostly from the Konkan. After migration to the city they had usually kept in touch with their place of origin and visited it at least once a year. Their wages are low, they are permanently in debt, and ninety-seven per cent of them live in one-room tenements which are dark and ill-ventilated. The factory hours for mothers range from eight to ten a day. The age-range of the women workers under consideration is 15-45 years and above, the highest percentage, 23.8, lying in the age-group 21-25 years, the next, 22.8 per cent, being in the group 26-30 years. The drop in numbers above twenty-five years of age, which becomes very marked above the age of thirty years, falling to 11.3 per cent, is generally due to the return of the women workers to their place of origin, permanently incapacitated by illness.

The average age of Bombay working women at the birth of the first child is eighteen years, the consummation of infant marriage, usually delayed until some time after puberty, taking place perhaps a little

later on the whole among the workers. It is believed that in Indian women child-bearing ceases early, so considerable time before the menopause, say at about thirty-five years, but inquiry into cases where the family is evidently complete shows that in the workers it takes place at about twenty-eight years. This is supported by further data which show that the average interval between births is 2.8 years, and that the average fertility, taking women more than thirty-five years of age, is 4.4. An examination of the data in the light of these two sets of facts suggests that the figure of twenty-eight years as the close of child-bearing represents a fact and is not due to an accidental selection. The authors consider two features in the statistics disquieting, namely, the early age at which child-bearing ceases and the fertility rate, which is so low in relation to the mortality rate of Bombay city. They point out that there is a danger that the 'working class' of Bombay will fail to keep up its number. To others, however, it may seem that industrial and housing conditions which appear to result in the permanent disablement of a large proportion of the female population at the age of thirty or thereabout even taking into account the early maturity of the Indian woman, and reduces the child-bearing age by seven years, are badly in need of investigation.

## Proposed International Congress of Anthropology

CORDIAL support has been given to the suggestion that a new international congress should be organised to cover anthropology and ethnology. Such a congress would meet the need created by the strict limitation of the field covered by the new International Congress of Prehistory and Protohistoric Sciences, which is to meet for the first time in London this summer. According to a communication from Prof. J. L. Myres which appears in *Man* for January, inquiries made on behalf of the Council of the Royal Anthropological Institute have not only elicited cordial expressions of approval, but also the matter has been taken up actively in Germany by Dr. E. Fischer. As the result of a consultation with his colleagues, he has written recently to the Council of the Royal Anthropological Institute to express the fullest approval on behalf of all the full professors of anthropology in Germany. They express willingness to concur in any arrangements the Institute may make for the formation of an international congress on the lines laid down last May for the Congress of Prehistory. It is suggested that similar statutes and constitution should be formulated, that the congress should be organised in two sections, one for anthropology and one for ethnology, that four languages should be officially recognised for the proceedings, and that meetings should take place at intervals of four years, preferably in the year in which the International Congress of Americanists meets in Europe. Such a date would provide for an alternation with the Prehistoric Congress, which will meet in London in 1932 and, probably, in Oslo in 1936. The first meet-

ing of the Anthropological Congress would take place when the next meeting of the Americanists is held in Europe, that is, in 1934. The Council of the Royal Anthropological Institute accordingly invites the anthropologists of all countries to co-operate in forming such a congress.

#### Isolation of Vitamin B<sub>1</sub>

In the second issue of the *Zeitschrift für Physiologische Chemie* for 1932, Prof. Windaus and his co-workers announce the isolation of the anti-neuritic vitamin B<sub>1</sub> in what appears to be the pure state. In 1926, Jansen and Donath reported the preparation from rice bran of a crystalline substance having the formula  $C_6H_{10}ON_2$ , which was believed to be the vitamin, but subsequent work, notably that of Jansen, Kinnersley, Peters, and Reader, in 1930, showed that the substance was not pure. In 1929, Windaus took up the preparation of vitamin B<sub>1</sub> from yeast, and in the initial stages of purification he followed well-known lines. From the neutralised raw extract he has recently prepared the gold salt, decomposed this with hydrogen sulphide, and from the filtrate isolated the picolonate, which is dimorphous. Analysis of the picolonate gave the surprising result that the vitamin contains sulphur as well as nitrogen; its formula is probably  $C_{12}H_{17}N_3OS$ . The hydrochloride was prepared, its absorption spectrum gave a maximum at 250-260  $\mu\mu$ , and its potency, determined on pigeons, was 1.4-3.3  $\gamma$ , as against 9  $\gamma$  found by Jansen and others for the substance isolated by the original method of Jansen and Donath. Prof. Windaus states his belief that he has now isolated the pure vitamin.

#### Structure of the Cell Nucleus

In his presidential address to the Royal Microscopical Society delivered on Jan. 20, Prof. R. Ruggles Gates reviewed present knowledge regarding nuclear structure, especially in relation to genetics. On the basis partly of investigations in his own laboratory, Prof. Gates believes that the nucleolus contains two substances, one of which enters the chromosomes in prophase and leaves them in the telophase of mitosis, and that the chromosome is a double structure throughout the mitotic cycle, a split of the chromonema occurring in metaphase for separation in the following metaphase. The chromonema is derived by the union of chromosomes in prophase, and during interkinesis the chromosome is represented by a double chain of chromomeres. From the evidence of karyomeres in animal cells, the nucleus is regarded as a compound structure, and it was further suggested that the spindle is also compound, the real unit in mitosis being a chromosome with its surrounding karyolymph, which becomes transformed into spindle fibres.

Prof. Gates discussed the relation of chromomeres to genes, pointing out that we have no real knowledge of why the chromosome behaves as a unit. He suggested that the chromosomes of Protista are undifferentiated along their length, and that genic mutations have led to their gradual differentiation, with

the probable result that genes are of different sizes. The gene is, however, not a representative particle but a physiological unit, the conception being necessitated both by the phenomena of crossing-over and of mutation. Each genic difference affects many or all parts of the body. Estimates indicate that the gene is of the same order of size as virus particles, and some at least cannot be composed of more than a few hundred molecules. The specific attractions which arise between chromomeres in meiosis belong to the level of organic rather than physical phenomena, and are at present wholly unexplained. Such conditions as high and low temperatures may inhibit this attraction, and genic mutations have arisen in which asynapsis occurs in one or in both sexes, leading to pollen or seed sterility. Prof. Gates stated that it is not at present clear exactly where the limitations of the gene theory lie.

#### The Expanding Universe.

In his Friday evening discourse at the Royal Institution on Jan. 22, Sir Arthur Eddington discussed the expansion of the universe. Outside our own galaxy of stars there exists a vast number of external galaxies, each containing many millions of stars, which appear as nebulae. These are to be found running away from us almost unanimously, and the farther away they are, the faster they recede. This effect has been observed up to a distance of more than a hundred million light-years, the speed there reaches 20,000 km. a sec.—as fast as an alpha particle. It looks at first as though the nebulae must have a particular aversion to us, but it is not difficult to see that the recession is the effect of a general expansion of the universe, and is not especially aimed at us. An effect of this kind has been anticipated theoretically. Einstein's law of gravitation contains a term representing repulsive force, which is ordinarily minute and negligible, but at very great distances the repulsion becomes large and overmasters the ordinary gravitational attraction, so that very remote objects tend to scatter apart. The theory, however, does not predict the magnitude of this 'cosmical repulsion', and hitherto it has only been possible to evaluate it from direct astronomical observations of the nebulae. Sir Arthur is convinced, however, that precisely the same cosmical term is concerned in the theory of the atom and supplies the standard which determines, for example, the radius of an atom. So that out of the theory of the atom (without any astronomical observations) we can predict the rate of recession of the nebulae, or alternatively, astronomical observation of the distances and velocities of the nebulae is a method of determining the masses of the electron and proton. Sir Arthur stated that, in his opinion, this astronomical phenomenon of the expanding universe is the main clue by which we can ultimately unravel the mechanism of the atom.

#### The Teleprinter

Speaking at the annual dinner of the Insurance Institute at Birmingham on Jan. 22, Sir Kingsley Wood, Postmaster-General, said that the Post Office hopes to introduce in a few months' time a tele-

printer exchange service. This system will probably be much used in the future by business firms. The new method enables letters, reports, and all kinds of messages to be type-written automatically between the offices of any two telephone subscribers, at any distance from one another. The typist in either office types the message, and it is printed simultaneously on the machine in the other's office. Both subscribers thus get a complete typed record of all the communications exchanged. The message can be sent at the speed at which the average typist works. To safeguard against wrong connexions, the sending subscriber presses the 'Who are you?' key. The distant machine at once transmits back its own exchange and number. The service will be available in London in the spring and in the provinces in the summer. Speaking of the British Industries Fair, Sir Kingsley Wood said that at the Castle Bromwich Section the Post Office would have an exhibit which would be connected with Olympia in London, so that the public could see how the system operates. The Post Office is apparently following out its new policy of advertising. We think this highly advisable, as much ill-informed criticism has recently been directed at it.

#### Pontifical Academy of Sciences

At the inaugural meeting of the eighty-fifth academic year of the Pontifical Academy of Sciences, on Dec 20, it was reported that His Holiness Pope Pius XI, who was present at the meeting, had decided on the erection of a new hall in which the meetings could be held. After the delivery of the president's introductory address, in which the scientific activities of the past session were briefly reviewed, the awards of the assessors on the twelve papers on "Mendel's Law and Chromosomes", submitted in competition for a prize of 10,000 lire, were announced. First place has been accorded to Prof. Paolo Enriquez, of the University of Padua, while the paper of Dr. Fraser Darling, of Edinburgh, and that of Prof. Carlo Jucci are considered worthy of special mention, and are to be published at the expense of the Academy.

A NUMBER of communications were then presented to the meeting of the Pontifical Academy. In a paper on so-called embryos of a foraminifer, E. Dervieux stated that organic remains similar to those described by Prof. De Lapparent in 1925 as embryos of *Logena* have now been found in a deposit dredged from a depth of more than 2000 metres near the Balearic Islands. Inertia of space was discussed by G. Gianfranceschi, and a new Sicilian species of the genus *Amphimallus* Latr. was described by P. Lugioni. Dealing with the subject of physical space, matter, and electrons, P. Giorgi expressed the view that the equations of the new physics have reconciled the photonic and undulatory conceptions, but are not yet definitive, as they take account neither of the equality of all electrons or of all protons, nor of the difference in mass between electrons and protons, and, moreover, do not seem adequately to interpret nuclear physics. An account is given by Neviani of the skeleton of *Globicephalus melas* found some years ago near Ladispoli.

In a note by G. Stein on the total lunar eclipse of Sept. 26—observed under ideal conditions at the Vatican Observatory—it is stated that the most striking feature was the appearance of the blueish luminous crescent, which showed no appreciable asymmetry with regard to the straight line joining the centre of the moon with that of the shadow. This phenomenon was also examined by M. Ananoff and referred to in NATURE of Jan. 23, p. 136. A paper entitled "Independence of Histogenesis and Organogenesis", by S. Ranzi, records interesting results connected with the development of pieces of the embryo of *Septa*. The rock samples and fossils collected by General Nobile in Franz Joseph Land were discussed by G. De Angelis d'Ossat, and the various radiations influencing vegetable tumours were classified by Vincenzo Rivera into those which enhance and those which depress the growth of such tumours. Other communications dealt with the occurrence of *Orbitolina* in North America (A. Silvestri), Insecta orientalia (L. Navàs), the proteases of the acido-proteolytes (C. Gormi), the study of equations by an extension of Abel's problem (Scatizzi), etc.

#### British Museum Acquisitions.

AMONG recent acquisitions by the Zoological Department of the British Museum (Natural History) are three Norwegian beavers and a specimen of the rare squid *Stenoteuthis caroli*, about 6.5 ft. long, stranded at Scarborough. It is interesting to find that the Norwegian beaver is still holding its own. A high percentage of the squids stranded in Great Britain are found on the Yorkshire coast. The Department of Geology has recently been enriched by the presentation, through the trustees of the Vernay-Archbold Expedition, of a large series of fossils collected by Dr. Errol I. White in Madagascar during 1929. The specimens are chiefly those of the sub-fossil fauna which became extinct probably within historic times, for mention of many of the creatures, some of which are remarkable for their great size, occurs in Malagasy folk-tales. Among the interesting specimens are the remains of the extinct Giant Lemur, *Megaladapis*, which has the largest skull of any known primate, and is peculiar in lacking the front cutting-teeth (incisors) in the upper jaw. A fragment weighing 1084 gm. of the rare pallasite type of meteorite of a new find near Alice Springs, MacDonnell Ranges, Central Australia, and various minerals and rocks collected by the donor have been presented by Dr. Herbert Basedow to the Department of Minerals. A large collection of co-types of Chinese species of *Rhododendron* have been presented by the Edinburgh Botanic Garden. These were from collections made by the late Mr. George Forrest, news of whose death in Yunnan reached England only a few days ago. Miss M. Brown has presented the British herbarium of her father, Henry Brown (1824-92). The herbarium was got together mainly while Henry Brown was a pupil of Isaac Brown, of Hitchin, who was a well-known naturalist and Lord Lister's first school-master.

### Breeding of Touracos in England

TOURACOS, of the species first to be made known to science (*Turacus persa*), were bred in England last year by Capt H S Stokes, who gives an account of his success in the *Avicultural Magazine* for January (p 3). The birds, which had made more than one unsuccessful attempt to breed before, hatched a young one in mid-July, which they brooded in turns, the cock taking the day shift, as with pigeons. As with these birds, too, the young was fed by regurgitation, and remained on the nest for some time, but here the resemblance ceased, for it was downy and left the nest and fed itself before it was fledged, with wing-feathers, however, developed, but showing white instead of the characteristic red on the primaries of this bird and its near allies in the touraco family. It was not until the bird was nearly full-grown that this red appeared by a gradual change in the colour of the feathers, this would seem to indicate that the characteristic copper-containing pigment, turacin, cannot be secreted by the young touraco until the demands of bodily growth have been practically met, and apropos of this red colour, it may be mentioned that in old stuffed specimens of touracos long exposed to light it becomes purple. The only species of the family bred here previously is *T. macrorhynchus*, a much less familiar bird, but it often happens in aviculture that the rarer species breed best.

### Luminosity of Fire-Flies.

WE have received a communication from Mr Edward T Dixon, of Billy Dun, Half Way Tree, Jamaica, regarding the luminosity of fire-flies in Jamaica. He mentions having observed large numbers of a species of fire-fly emitting flashes of light in rhythmic unison, a feature, it may be added, that has been noted in other lands. In the Jamaican species the flashes were emitted at intervals of just under three seconds duration. Mr Dixon mentions having seen half an acre or more of a grass field lit up brilliantly by the flashes of fire-flies so that the shrubs and hedges were revealed. During the intervals between the flashes nothing was visible in the prevailing darkness. Little is known regarding the phenomenon, and experimental observations with reference to the co-ordination of light emission by these insects might prove of great interest.

### Centenary of the *Nautical Magazine*

THE *Nautical Magazine* this year commemorates its centenary, and the January issue is therefore devoted mainly to a review of the progress of nautical matters during the last hundred years. The journal was founded in 1832, and edited for thirty-eight years, by Commander (afterwards Rear-Admiral) A B Becher, an officer who served for many years under Beaufort, the hydrographer to the Navy. The original prospectus of the magazine stated that its contents would be arranged under the four heads, hydrography, voyages, navigation, and nautical miscellany, while on his retirement Becher said that the aim of the magazine had been "to aid anything which might contribute to the seamen's benefit." Many eminent men of science have contributed to its pages. The names of Sir John

Franklin, Lieut Henry Raper, Sir W Snow Harris, Lieut M F Maury, James Glaisher, Sir William Thomson (afterwards Lord Kelvin), and Lord Brassey are all to be found among the contributors of the first half of the magazine's career, while in more recent times articles have appeared signed by distinguished officers of both the Royal Navy and the Mercantile Marine. Recognised all over the world as the magazine of the merchant service, the *Nautical Magazine* has faithfully reflected all the aspects of maritime affairs, the scope and interest of which are well illustrated by the series of articles on navigation, ships, education, meteorology, and other subjects in the centenary number.

### Road Traffic Signalling

WE learn from *Roads and Road Construction* for January that upwards of five hundred million pounds has been spent in roads and road construction during the past ten years. It is also stated that the work has neither been scientifically considered nor directed in relation to those chiefly concerned. The special aspect of road traffic signalling was considered at the Institution of Civil Engineers on Dec 9. In opening the meeting, Major Aldington laid stress on the importance of extending the automatic signalling system to highways. This would expedite the movement of traffic and so would lead to economies. In the London area alone, £450,000 is spent annually in the provision of police to regulate the traffic at the points of intersection of roads. The provision of facilities for roundabout working and electric signalling would be a boon to drivers and would materially reduce the number of accidents. The discussion largely centred round the visual signal system adopted in Oxford Street. Some of the speakers suggested that the amber light should be regarded as the signal for pedestrians. Much was said in favour of a gyratory system being adopted in Oxford Circus. It was stated that the abolition of right-angled turns would be certain to make the traffic more fluid. It is also common knowledge that the traffic up Harewood Place, across Oxford Street, is often prevented from moving at certain times of the day, although the green lights are showing, by the crowds of pedestrians in Oxford Street. A model for the automatic control of signals at crossings was shown to the meeting, the signals being operated by the traffic.

### Steam Research in Europe and America.

UNDER this title, Dr Ing Max Jakob last May delivered a course of four lectures under the auspices of the University of London. Constituting as they did a valuable up-to-date review of the experimental work of recent years, the lectures have been prepared for publication since being delivered, and have been printed *in extenso* in *Engineering* in eight sections during July-Dec 1931. The first lecture dealt with the fundamental thermodynamical properties of water and steam, including the mechanical and thermometric direct measurements of pressure, temperature, and volume, the second with the calorimetric, direct measurements of sensible and latent heat contents, the third with the optical measurements by which attempts have been made to determine the specific

heat at high temperature, and the development of the steam tables in different countries, while the fourth lecture was a survey of some special problems of steam research such as evaporation, condensation, heat transfer, and heat radiation. Reference was made to the international co-operation on steam research suggested by the British Electrical and Allied Industries Research Association, while at the beginning of his lectures Dr Jakob paid a tribute to the late Prof H L Callendar, who had, he said, comprehended and mastered the whole science of thermodynamics of water and steam more fully than anyone else in the world.

#### Pendleton Earth-shake of Jan 16.

AT about 12 30 A.M. on Jan 16, slight earth-shakes were felt in the mining district around Pendleton, near Manchester. The intensity was less than usual (degree 4, Rossi-Forel scale). The disturbed area was roughly circular, about four miles in diameter, with its centre close to the line of the Irwell Valley fault, and about two miles north-west of Pendleton. There can be little, if any, doubt that the earth-shakes of this district are caused by slips along the fault due to the withdrawal of the coal or to other mining operations. The chief interest of the recent shocks is that they disturbed almost exactly the same area as one did on Feb 27, 1899. On April 7, 1900, a similar shock occurred with its centre a short distance to the south-east, and on Nov. 25, 1905, and May 3, 1931, much stronger shocks, with their centres close to Pendleton, or nearly two miles south-east of the centre of the latest shock.

#### Announcements.

At the annual general meeting of the Royal Meteorological Society on Jan. 20, the following officers were elected for 1932. *President*, Prof S Chapman, *Vice-Presidents*, Dr C. E. P. Brooks, Mr C. K. M. Douglas, Mr J. Fairgrieve, Mr. R. G. K. Lempfert; *Secretaries*, Dr J. Glasspoole, Mr W. M. Witchell, Dr. A. Crichton Mitchell, *New Members of Council*, Lieut.-Com T. R. Beatty and Mrs C. J. P. Cave.

THE following have been elected officers of the Royal Microscopical Society for 1932. *President*, Mr Conrad Beck, *Vice-Presidents*, Mr A. Earland, Prof R. Ruggles Gates, Mr J. Rheinberg, Dr G. S. Sansom, *Treasurer*, Mr C. F. Hill, *Secretaries*, Mr J. E. Barnard, Prof. R. T. Hewlett, *Hon. Librarian*, Dr Clarence Tierney, *New Members of Council*, Prof D. M. Blair, Mr S. H. Browning, Mr B. K. Johnson, Mr A. More, Mr J. Smiles, Mr H. Wrighton.

THE present programmes of standard frequency transmissions on the first and third Tuesday afternoons of each month from the transmitting station 5 H.W., at the National Physical Laboratory, have now been discontinued. They will be replaced by specially modulated transmissions in accordance with a programme which will be announced at a later date. The three-monthly evening transmission on 1785 Kc/s will be continued as at present. Particulars of this transmission can be obtained from the Department

of Scientific and Industrial Research, 16 Old Queen Street, London, S.W.1.

At the recent annual meeting of the Botanical Society of America, the following officers were elected for 1932. *President*, Prof G. J. Peirce, Leland Stanford University, *Vice-President*, Prof A. J. Eames, Cornell University, *Secretary*, Prof S. F. Trelease, Columbia University. The following botanists were elected as corresponding members. Prof P. A. Dangeard, The Sorbonne, Paris, Prof Ludwig Diels, University of Berlin; Prof H. H. Dixon, Trinity College, Dublin; Prof K. Miyabe, Hokkaido Imperial University; and Prof F. Oltmanns, University of Freiburg im Breisgau.

MESSRS Dulau and Co., Ltd., 32 Old Bond Street, W.1, have just issued a catalogue (No 194) of nearly five hundred second-hand works of botanical interest, obtained chiefly from the library of the Royal Botanic Society of London. The prices asked appear very reasonable.

THE two large catalogues of chemical and physical apparatus issued by Messrs F. E. Becker and Co. (W. and J. George, Ltd.) are well known in laboratories. This firm has now drawn up a 72-page supplementary catalogue on the same lines as the general catalogues, including only laboratory equipment made in Great Britain, and much of it in Messrs. Becker's own works. The reputation of British scientific instruments has grown rapidly in recent years and with it the range and scale of production. As a consequence Messrs Becker are now able to state that, with the exception of furnace-made glassware, porcelain, and similar articles, they are practically independent of outside sources. The present catalogue certainly seems to include all the ordinary equipment of a laboratory.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned.—A lecturer in radiology in the University of Liverpool—The Registrar, the University, Liverpool (Jan 31). An assistant medical officer at the Radium Institute, Manchester, for dealing largely with radium and deep X-ray cancer therapy in the Institute and Associated Hospitals—The Hon. Secretary, Radium Institute, Manchester (Feb 2). Two mechanical engineers in the Ordnance Factories, Royal Arsenal—The Chief Superintendent of Ordnance Factories, Royal Arsenal, Woolwich, S.E. 18 (Feb 5). A biochemist at the Selly Oak Hospital, Birmingham—Dr R. P. S. Kelman, Selly Oak Hospital, Birmingham (Feb 10). A sub-editor of the *British Journal of Radiology*—The General Secretary, British Institute of Radiology, 32 Welbeck Street, W.1 (Feb 20). A professor of zoology in McGill University, Montreal, Canada—The Secretary, McGill University, Montreal, Canada (April 1). A lecturer in philosophy at Exeter College, Oxford—The Rector, Exeter College, Oxford (May 14). A Dr Robert Pollok lecturer in materia medica and therapeutics in the University of Glasgow—The Secretary, University Court, the University, Glasgow.

## Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

## Theories of Muscular Contraction

SINCE Lundsgaard showed that the contractile mechanism can work without production of lactic acid and that this acid, when formed, appears mainly, perhaps entirely, after contraction is over, the one remaining important chemical change, the breakdown of phosphagen (phosphocreatine) is generally supposed to precede and cause contraction. This view, however, scarcely accounts properly for the observed behaviour of muscles poisoned with iodoacetate. In such muscles, when stimulated in nitrogen, exhaustion of the phosphagen supply brings to an end the only available exothermic reaction and the muscle fails to respond, but it does not fail to contract, *it fails to relax*, for it remains in a state of contraction ('rigor') developing a tension not far short of a maximal twitch. It seems more natural to conclude that the chemical reactions accompanying activity are primarily concerned with relaxation and occur after contraction, this is to say, they represent stages in a 'recovery process' as that term has been applied to processes in nerve.

When Fletcher and Hopkins had exploded the 'inogen' theory of contraction, it was assumed that the sequence of events must be (1) excitation, (2) an exothermic chemical reaction, (3) contraction. It was therefore supposed that in resting muscle the contractile mechanism (whatever its nature) was at zero energy potential and that the exothermic reaction 'charged up' the system to high potential, thereby producing a structure tending to be of shorter length. Relaxation was the result of dissipating the energy and returning to zero potential. The theory here suggested is the opposite and is a partial return to the 'inogen' theory. In resting muscles the contractile mechanism is supposed to be at a steady high potential, maintained by the resting metabolism. On excitation, the potential falls to zero and the muscle tends to a shorter length. It then relaxes because the contractile mechanism is recharged to its original potential by what is essentially a speeding up of chemical changes occurring the whole time. In quick moving muscles the recharging is begun by the rapid process of phosphagen breakdown, in slower muscles other slower reactions may perhaps replace the phosphagen mechanism.

The terms 'charge' and 'discharge' are intended to suggest the analogy of an electrical condenser. The contractile mechanism may well consist of longitudinally arranged and electrically polarised surfaces. If these are extensible, the repulsive forces of the electric charges will make them longer when charged than discharged. A mechanism of this sort is similar to that generally supposed to be concerned with the excitation process in nerve. However, the main point is quite independent of any particular type of physical mechanism imagined to exist in the muscle and is a matter of the time relations of the chemical reactions.

The theory here suggested, 'Charged at Rest', seems to fit the facts at least as well as the alternative 'Discharged at Rest', and in some cases better. As already mentioned, it gives a more accurate account of the phenomena of the iodoacetate muscle. It provides a function for the resting metabolism and

explains why the metabolism of activity and of rest differ quantitatively rather than qualitatively. Again, it fits in better with the phenomena of the refractory period after excitation. If each excitation discharges the contractile mechanism to zero potential, a second discharge is impossible until recharging has begun, and the second discharge will be smaller than the first until the full potential is reached. On the 'Discharged at Rest' theory there is no reason to expect a refractory phase. Lastly, if, as seems likely, the initial resting state is more unstable the higher the potential, it is easy to see how some muscles can be self-exciting and others not. That is to say, the difference between heart and skeletal muscle is that in the heart the recharging process is slow (long refractory period) but tends to charge the mechanism up beyond the level at which it is stable. In skeletal muscle the recharging is rapid but never exceeds the level at which extra energy has to be provided by an external stimulus to discharge the mechanism.

## Inheritance of Milking Capacity.

A STUDY of the milk yields of the progeny of 728 bulls of the Red Danish breed has been made with a view to determine—first, the ability of each bull to transmit the different degrees of milking capacity, and secondly, having thus obtained an index of this ability, to determine the extent to which it was influenced by the various animals in his pedigree. The average number of daughters to each bull was 18. The figures were taken from the annual reports of the Milk Recording Societies throughout Denmark for 1918–1931. The daughters' yields were mainly calculated on the average of the first two lactations and corrected to the third lactation. The records of the dams and grandams were based on as many lactations as possible, from three to ten, and averaging 5.5. The average of these uncorrected lactations was taken as an indication of the milking capacity of the dam or grandams.

To measure the genetic aspect of the ability of bulls to transmit milking capacity, correlations were made of the average yields of the daughters of these

" " " of butter-fat = 179.64 kgm,  $\sigma = 20.48$

bulls to the average yields of the daughters of their sires, and to the actual yields of their dams and grandams. Thus the milking capacity of the bulls (as measured by the yields of their daughters) has been correlated to the milking capacity of the sires and grandsires (similarly measured) and to the dams and grandams (as measured by actual production). These correlations are as shown in the accompanying table.

It is to be noted that the genotypes of the bulls have been compared to the *genotypes* of their male ancestors but to the *phenotypes* of their female ancestors. Hence the correlation figures to the male ancestry cannot be directly compared with those to the female ancestry.

It will be seen that as regards milk yield the paternal grandsire has an effect equal with the maternal grandsire, though as regards butter-fat yields the maternal grandsire is of slightly greater importance. This can be accounted for by the methods employed by the breeders, who for the past fifteen years have, through an intelligent appreciation of the value of the progeny test, paid almost exclusive attention to the male line. From a study of the records of the progeny of the two grandsires and the deviation of the yields of their daughters, it was found that the more highly selected bulls which appeared as paternal grandsires were distinctly more homozygous for the factors affecting the transmission of milking capacity than were the less highly selected maternal grandsires.

There is, however, a highly significant difference between the correlation figures to the two grandams. The correlation to the paternal grandam is practically nil, while that to the maternal grandam is significant.

Smith, Scott, and Fowler,<sup>1</sup> working with correlations of Ayrshire cows to their ancestors, found a significantly lower correlation to the paternal than to the maternal grandsire, and from this deduced the possibility that sex-linked factors might be involved. In the present study, the correlation to the two grandsires is approximately the same, but a difference is found between the correlations to the two grandams. The present study is of *bulls* and their ancestry. A character inherited in a sex-linked manner cannot be transmitted to a bull from his paternal grandam. (But a paternal grandam can transmit sex-linked factors to her granddaughters.) Accordingly, in the present work the test as to whether sex-linked factors are involved in the transmission of milking capacity depends on whether or not there is in this respect a difference between the correlations of the bull to his two grandams. This has been found to be the case. Thus, while from these figures it can be demonstrated that autosomal factors are concerned in the transmission of milking capacity, it is also clearly shown that this capacity is to no small extent conditioned by factors inherited in a sex-linked manner.

#### Field Studies and Physiology: a Correlation in the Field of Avian Reproduction

ELIOT HOWARD,<sup>1</sup> in his classical field studies on the behaviour of the warblers, buntings, and other passerine birds, has pointed out that whereas the male has what we may call two *phases* of sexual behaviour—neuter and full male—the female has three, for she passes from the neuter phase of winter to full femaleness by way of a partly-sexed phase. During this intermediate phase she seeks out the company of a male, appears interested in various of his advances, and may construct the outer shell of one or several nests. But it is not until the fully-sexed phase that she will solicit or permit coition, or will construct a lining for a nest. The fully-sexed phase begins about 3-6 days before the first egg is laid.

Meanwhile, Riddle<sup>2</sup> and his associates, working

with ring-doves (*Peristeridae*), has found a remarkable set of physiological changes associated with ovulation in the female, and all taking their origin about four and a half days before the first egg is *ovulated* (that is, rather more before it is *laid*). The blood-sugar rises 20-25 per cent, the weight of the adrenals hypertrophies by about 40 per cent; the blood calcium rises about 100 per cent, the oviducts enlarge by about 800 per cent, the histological picture of the thyroid changes from rest to marked activity; the blood-fat goes up by about 35 per cent and its contained phosphorus by about 50 per cent, and the egg (oocyte) itself suddenly begins to grow about twenty-five times as fast as before, and to put on yellow yolk in place of white. Doubtless general ovarian function also alters. All these changes reach their maximum at about the time of ovulation, except those involving fat and phosphorus, the maximum of which is about 2-2½ days before first ovulation.

Very similar changes occur in pigeons (*Columbidae*), the change in growth-rate of the yolk of the egg occurs also in fowls and in ducks (Chomovič<sup>3</sup>), but here 5-8 days before ovulation.

From the facts concerning the onset of changed growth-rate of the yolk in fowls and pigeons, it is clear that the physiological change begins earlier and lasts longer in birds of a large size. In small passerines it would be presumed to begin not more than 3-4 days before ovulation or 4-5 days before laying.

It will, then, be seen that there is evidence of a striking physiological change occurring in certain female birds just about the moment in the reproductive cycle when a striking change in sexual behaviour occurs in other species and it is, I think, legitimate to connect the two. The physiological change is, apparently, chiefly endocrine in nature, involving thyroid, adrenals, parathyroid, ovaries, and presumably pituitary. The correlated alteration in behaviour is of great interest in regard to sexual selection, for if in its absence the female will not permit coition, although the ovary is sufficiently active to induce some interest in birds of the opposite sex, we have an explanation of most of the many records where observers are puzzled by the apparent failure of male courtship-display to attain its end of stimulating the female to coition.

In any event, it seems worth while pointing out this interesting convergence of two quite independent lines of study.

#### Photoelectrons and Negative Ions.

PROF. WELLISH's recent communication<sup>1</sup> calls for some comment, as he states that the experiments with photoelectric currents in dry air which he describes show that over the range of pressures 7 mm. to 760 mm. "the great majority of negative ions are formed in the vicinity of the electrode at which the electrons originate", a conclusion which is not in agreement with many other experiments made in Sydney and elsewhere.

Some of these experiments are described in the issue of the *Philosophical Magazine* for October 1925, p. 825, where the method used was specially designed to measure the coefficient of attachment  $\alpha$  (Prof. Wellish denotes this quantity by  $\lambda$ ) of electrons which move in a gas at a pressure  $p$  under a uniform electric force of intensity  $X$ .

The values of the ratio  $a/p$  with dry air then obtained have been confirmed more recently in some experiments by a method, yet unpublished, in which the nature of the photoelectric stream is examined at various distances from its source while the pressure and electric force are kept constant. With dry air and several other gases this method showed that for appropriate values of pressure and electric force the nature of the stream changes progressively with the distance from its source.

These experiments were not designed to give information about the formation of negative ions near the emitting surface, but by means of the theory and observations given in 1925 it is easy to calculate an upper limit for the ratio of the number of ions formed initially to the number formed in the gas. Such a calculation shows, for example, that this ratio is less than one in dry air at a pressure of 22.6 mm with an electric force of 10 volts/cm. Moreover, if Prof. Wellish's conclusions be true, it would be practically impossible in any of these experiments to observe the attachment of electrons in the gas.

With regard to the evidence adduced by Prof. Wellish, it is remarkable that the curves *A* and *B* in his diagram are less consistent with his own views than with the theory that negative ions may be formed quite as notably in the gas as near the cathode. This is shown clearly in Table 1, where the observed values of the ordinates  $y_A$ ,  $y_B$  (for the curves *A* and *B* respectively) for different values of the abscissa  $x$  are compared with values calculated on the two theories.

TABLE 1

Constants adopted: mobility  $k=1.8$ ,  $f_A=0.5$ ,  $f_B=0.52$

| $x$  |                          | $y_A$ | $y_B$ | $a$  | $\theta$ |
|------|--------------------------|-------|-------|------|----------|
| 0.01 | Observed                 | 0.49  | 0.35  |      |          |
|      | Theory of attachment     | 0.486 | 0.35  | 0.15 | 0.84     |
|      | Theory of non-attachment | 0.483 | 0.35  | 0    | 0.67     |
| 0.02 | Observed                 | 0.45  | 0.22  |      |          |
|      | Theory of attachment     | 0.448 | 0.22  | 0.20 | 0.60     |
|      | Theory of non-attachment | 0.440 | 0.22  | 0    | 0.42     |
| 0.04 | Observed                 | 0.375 | 0.13  |      |          |
|      | Theory of attachment     | 0.376 | 0.13  | 0.50 | 0.64     |
|      | Theory of non-attachment | 0.344 | 0.13  | 0    | 0.25     |

TABLE 2

| $X/p$               |         |      |       |
|---------------------|---------|------|-------|
| $(a/p) \times 10^3$ | Wellish | 0.85 | 0.424 |
|                     | Bailey  | 2.5  | 3.4   |
|                     |         | 2.1  | 3.1   |

In Table 2 a comparison is made between the values of  $a/p$  thus deduced from Prof. Wellish's experimental results and two values obtained by me in 1925, and this shows good agreement between them.

If the value adopted for the ionic mobility be 2.1, similar calculations show that the theory of attachment in the gas is still in better agreement with the above observed values of  $y_A$  and  $y_B$  than is the other, but less markedly so than is shown by Table 1.

It may then be concluded that for air pressures up to 59 mm the formation of negative ions by attachment of electrons to molecules in the gas is no less notable a process than the formation of negative ions near the cathode.

### Spectroscopic Evidence of Arsenic Hydride.

Messrs Kimball and Bates<sup>1</sup> have recently described some bands, emitted by a carbon arc, running in an atmosphere of hydrogen. The negative electrode was drilled and filled with arsenic. Because of this, the authors consider the bands to be due to AsH and As<sub>2</sub>. I find, however, strong arguments for the bands being identical with the CH bands  $\lambda 3143$  Å, already investigated by Fortrat<sup>2</sup> and Hori<sup>3</sup>. Even the conditions of activation, mentioned by Kimball and Bates, agree with my conclusions; namely, that the bands were missing when the arsenic was placed in the positive carbon. This can be explained by the fact that the presence of a metal in the positive carbon strongly reduces the temperature of the arc, and the activation of the CH bands is very sensitive for the temperature.

The unresolved band at  $31802.6 \text{ cm}^{-1}$  is surely identical with the *Q* branch in the CH band. The measurements of Fortrat are in good agreement with this, as well as with the values calculated from the formula of Kimball and Bates. In Hori's measurements a constant error appears, owing to the low dispersion used by him. Mr T. Heimer, photographing the CH band in the second order of the 6.5 m concave grating in this laboratory, also finds this error in Hori's measurements.

Directly repeating the experiments of Kimball and Bates, I find no signs of a band spectrum due to AsH.

### The Spinning Photon and its Scattering by Molecules.

THE observed fact that a molecule in scattering light may change its state of rotation, itself conveys the suggestion that the photon has an intrinsic spin, the alternative explanation of a conversion of the linear momentum of light into the angular momentum of the molecule during the collision being *prima facie* highly improbable. The suggestion gains strength when we notice how simply the conception of the spinning photon explains both the selection rules in Raman scattering and the accompanying phenomenon of the reversal of circular polarisation. Nevertheless, to the critically minded, such considerations may fail to carry complete conviction. The reality of photon spin is, however, established<sup>1</sup> by quantitative studies of (1) the intensity of the lines in the rotational Raman spectra of gases, (2) the depolarisation of the Rayleigh scattering when separated from the rotational scattering. The Kramers-Heisenberg theory of dispersion as developed by Mannebeck<sup>2</sup> fails to give correct results on both of these points, while a modified theory based on the concept of the spinning photon meets with complete success.

A further test of the theory of the spinning photon is furnished by quantitative studies of the state of polarisation of the vibration lines in Raman spectra. In certain simple cases, it is possible to associate these lines with linear modes of the vibration of the molecule. Each such vibration line should be accompanied by faint rotational companions on either side of it, the ratio of the intensity of which to that of the parent line is determined by the state of polarisation of the latter. The change in the depolarisation of the Raman line, when measured with a Nicol and a spectrograph, using alternately a very wide and a very narrow slit, enables this ratio to be determined. As

an example, we may mention the case of the strongest vibration line in the spectrum of liquid carbon disulphide. Careful measurements, using a pointolite mercury lamp and photographic photometry, indicate the depolarisation of this line with a fine slit to be 18 per cent. Manneback's theory indicates that the depolarisation should increase, when a very wide slit is used, to 44 per cent, while the theory of spinning photons gives it as 26 per cent. The latter is in close agreement with the observed value, which is 25 per cent.

It is well known that some vibrational Raman lines show very large depolarisation. Bar<sup>3</sup> and Hanle<sup>4</sup> have observed that such lines exhibit the phenomenon of reversal of circular polarisation. In terms of the theory of photon spin, we must assume that in such cases the molecule takes up angular momentum from the incident light in some manner otherwise than by its rotation as a complete entity. Internal spins or rotations within the molecule associated with such modes of vibration have to be postulated. The familiar example of a vibrating string or rod which describes circles or ellipses may help in picturing this state of affairs.

#### Behaviour of Pyroelectric Crystals.

IN some simple demonstration experiments using liquid air we repeated many of the interesting observations reported by L. Bleekrode<sup>1</sup> and by Miss M. E. Maurice<sup>2</sup> on the demonstration of electric lines of force around pyroelectric crystals. As these papers may have escaped the notice of some mineralogists and crystallographers, we feel it may be helpful to direct attention to what, in our estimate, is the simplest and most striking way of demonstrating the phenomenon of pyroelectricity.

As it came to our notice that at least some mineralogists have considerable difficulty in showing this phenomenon by the well-known method due to Kundt, which consists in dusting finely pulverised red lead and sulphur over the crystal as it cools, we employed this process, taking all the precautions mentioned by Dana<sup>3</sup> to ensure success. Although Dana refers to this method as "very convenient and simple", we consider that Bleekrode's method, in which the low temperature of liquid air is utilised, has advantages over it in this respect. Further, our experiments, using Kundt's method, did not show the effects predicted at all clearly; in fact, we obtained convincing results only in certain simple cases, for example, with a long tourmaline crystal possessing one polar axis.

In contrast to this, the behaviour of a crystal after immersing it in liquid air leaves no doubt as to its pyroelectric nature. The directed growth of the whisker-like ice filaments which form on the polar surfaces of pyroelectric crystals as they warm in air is striking, especially when viewed through a low-power microscope. The shooting off of portions of the ice filaments along the lines of electric force is most marked about a minute after these crystals begin to form. Although we observed the phenomenon clearly with tourmaline and quartz, it was best shown by a small boracite crystal with cubic, rhombic, dodecahedral, and positive and negative tetrahedral faces. Clouds of small ice projectiles passed during a limited period between one set of tetrahedral faces

possessing a positive charge and the other negatively charged set. Even with a tourmaline crystal about 4 cm long, small particles were shot from one pole to the other. By means of an electrified rod, it was easy to show the nature of the poles with this crystal.

In her paper (*loc cit*) Miss Maurice described a new method for measuring the electric moment of a tourmaline crystal, in which the crystal was deflected by an electric doublet. We made an approximate determination of this quantity simply, by suspending the crystal from a single silk thread and then determining its period of vibration in the uniform electric field existing between two large parallel plates in air. In two successive trials the electric moment obtained was 31.3, 31.6 esu and the charge on each end 11.2, 11.3 esu, the crystal having cooled after being discharged in each case through about 150°C. The minimum period occurred after twenty minutes' cooling, and it was used in the calculation. As no special precautions were taken to prevent leakage from the crystal, the absolute values have little significance.

My thanks are due to Mr C. A. Jarman for assistance with these experiments, and to Prof W. N. Benson, who lent the crystals.

#### Microscopic Cracks produced by Electric Spark.

IF a thick electric spark is made to glide along the surface of a piece of an ordinary window glass, a faint trace of the spark track is left on the glass surface. On examining this track under microscope, we find a large number of hair-like cracks running

FIG. 1.—Cracks on a cleavage surface of rock salt crystal produced by repeated sparking. Spark length, 3 cm., capacity 15 m.  $\times 150$

roughly parallel to each other and transverse to the axis of the track. It is interesting to observe that the cracks undergo further development even if left undisturbed. Minor secondary cracks gradually appear, filling up the space between the primary cracks with complicated networks. A thin surface layer bounded by these cracks begins to be peeled off, showing thus a mosaic of Newton rings. This latter pattern becomes visible an hour after the sparking and is most marked along the middle zone of the track.

Using a cleavage surface of rock salt crystal instead of the glass surface, a fine pattern of rectangular cracks is obtained (Fig 1). Other crystals give different but characteristic patterns, though not always coinciding with the usual cleavage cracks. The breadth of the zone of cracks increases with the capacity of the spark circuit. The relationship between the density of cracks and the capacity and the potential difference is not simple. The appearance of the cracks is probably due to the electrostatic stress acting as a superficial tension along the spark track. It seems that the present phenomena may be utilised for measuring the steepness of the potential gradient along the spark track.

Details of the results of experiments will be published later in the *Scientific Papers* of our Institute.

### Character of Atmospheric Ionisation.

IN recent months an apparatus has been set up at Kew Observatory for investigating atmospheric ionisation. A continuous record is taken of the ionisation currents to the central electrodes of three cylindrical condensers, through which air is aspirated. The outer cylinders of the condensers are maintained at three different voltages, which are automatically reversed in sign every five minutes, so that positive and negative ions are alternately collected by the central electrodes. The ionisation currents are recorded photographically on bromide paper by light reflected from the mirrors of three Dolezalek electrometers. The mouths of the condensers project through the wall of a hut and are 10 cm apart from each other. The mean height above the ground, a grass lawn, is 1.5 metres.

A quite unexpected phenomenon has been observed on the photographic traces. So far as can be seen, the ionisation current consists of a succession of pulses which occur simultaneously on all three current records. The magnitude of the effect varies with atmospheric conditions and from one pulse to the next. About twenty such pulses are recorded by the electrometers in each four minutes of charging up, that is, the frequency is five per minute on the average. In fine weather conditions, each electrode collects about  $10^8$  ions in four minutes, so that each pulse contains on the average about  $5 \times 10^6$  ions. Further, a proportionality exists between the pulses on the three instruments, a large 'kick' on one electrometer is accompanied simultaneously by large 'kicks' on the other two.

The Dolezalek electrometers are not critically damped, so it is impossible at the present stage to make accurate measurements of the succession of electrometer 'kicks' which constitute for the most part the current traces. It is intended to utilise a Lindemann electrometer, which is practically dead beat, for obtaining more exact information on the nature and magnitude of the pulses.

The results can only be interpreted as evidence that the ionisation in the bottom layer of the atmosphere is by no means uniformly diffused. Parcels of relatively highly ionised air are present which are of such a size that when one condenser receives a charge-pulse so do the other two. It is not possible to give the number of ions comprising a parcel, one can only point out that the fraction which each condenser collects may be from  $10^6$  to  $10^7$  ions. For comparison, we note that an  $\alpha$ -particle produces about  $2 \times 10^6$

pairs of ions in its path through air at atmospheric pressure, each parcel of ions in the atmosphere probably contains about a thousand times this number.

The phenomenon is yet to be explained, but one feels that the picture it has suggested of ions in parcels distributed more or less regularly through the atmosphere must modify considerably our ideas in atmospheric electricity.

### Polish on Metals.

SIR GEORGE BEILBY<sup>1</sup> attributed the polish on metals to the covering over of the surface by a layer of amorphous metal resulting from rubbing, which causes the metal to flow and then harden as a supercooled liquid. Prof G P Thomson's high-speed electron beam camera<sup>2</sup> was used to investigate this.

Small blocks of copper and silver were etched and pictures taken which showed diffraction rings corresponding to the spacings in the cubic lattice of each metal. The copper block was rubbed successively on emery papers No 00, No 000, and No 0000, with benzene as a lubricant to prevent the abrasive from being forced into the metal. At this degree of polish the diffraction rings were diffuse but of the same atomic spacings. As crystals normally give sharp diffraction patterns, the rubbing must have decreased the original size of the crystals, which reduced their resolving power and so caused the rings to broaden.

After polishing with light magnesium oxide and water, the mirror-like surface gave only two broad diffraction rings in place of the previous diffraction rings. The spacings of the copper atoms were now different from those in the crystal structure. The copper atoms must have been flowed into a random arrangement different from their orderly positions in the cubic lattice. But the atoms can approach each other only to a finite distance which will predominate, so that this new semi-orderly arrangement will be favourable for electron diffraction interference.

Fig 1

The intensity of the diffracted electrons  $I$  depends on the factor  $\psi$ , the amount that a single copper atom diffracts as the angle of incidence varies, and on the factor  $x$ , a function of the distance between the copper atoms, the angle of incidence, and the wave-length of the electrons  $I = 2\psi^2(1 + \sin x/x)$ . A microphotometer record of the two broad rings from polished copper is shown in Fig 1.

### NEAREST DISTANCE OF APPROACH OF ATOMS

|        | Calculated from<br>diffraction expts | In normal crystal<br>(X-rays) |
|--------|--------------------------------------|-------------------------------|
| Copper | $2.585 \times 10^{-8}$ cm            | $2.54 \times 10^{-8}$ cm      |
| Silver | $2.718 \times 10^{-8}$               | $2.876 \times 10^{-8}$        |
| Iron   | $2.667 \times 10^{-8}$               | $2.78 \times 10^{-8}$         |

These broad rings also appeared from a stainless steel mirror classed above as iron, and from silver and

copper polished with rouge and water. Some specimens were washed in absolute alcohol, others in benzene, and others in water before being photographed. When rouge was used without a quantity of water it became embedded in the metal surface, as shown by Mr B K Johnson using an immersion microscope, and also by the diffraction photographs showing the normal crystal pattern sharply plus additional rings given by the rouge.

### Magnetism of Precipitates of Colloidal Silver.

In a series of contributions <sup>1</sup> it has been shown by us that the magnetic properties of graphite, antimony, bismuth, and gold are modified by colloidalisation.

We have recently investigated two forms of colloiddally precipitated silver. In one method, a dilute solution of silver nitrate was reduced by tannin after adding sodium carbonate. In the second, a dilute solution of the same salt was reduced by hydrazine hydrate. The colloids were coagulated, washed, and dried in vacuum desiccators, precautions being taken to avoid oxidation and impurities. In the former method the specific susceptibility of two specimens was  $0.166 \times 10^{-6}$  and  $0.133 \times 10^{-6}$ , in the latter method, one specimen had a specific susceptibility of  $0.166 \times 10^{-6}$ . (The specific susceptibility of silver in the massive state is  $0.2 \times 10^{-6}$  at atmospheric temperature (I.C.T.)) The maximum size of the particles was about  $10\mu$ . Further attempts are being made to grade the particles and obtain more accurate information.

The hypotheses suggested in the note <sup>2</sup> on a similar phenomenon observed in the case of gold are also applicable to silver. Gold and silver are known to possess paramagnetic atoms, but build up diamagnetism only in the massive state. Changes depending on their crystal and block structure can therefore be expected in them.

### Photosynthesis of Carbohydrates *in Vitro*.

In a recent paper on this subject, <sup>1</sup> unsuccessful attempts by me to repeat the work of Baly <sup>2</sup> were described. It was not mentioned, however, that consideration had been given to the possibility of the failure to detect any photosynthetic sugars being due to the adsorption of these sugars on the large surfaces exposed by the catalyst powders. The catalysts were, in fact, repeatedly examined for the presence of any organic matter. The kieselguhr supported catalysts and the nickel carbonate were, after use in the photosynthetic tests, heated for some hours with water, and also with absolute alcohol, under reflux. On subsequent evaporation of the water or alcohol, no organic residue was obtained. Tests for charring with concentrated sulphuric acid on the catalysts gave negative results.

In addition, estimations of organic carbon were made, by the method described, on the nickel carbonate after use as a catalyst, but no trace of organic matter was found. Control experiments in which sucrose was estimated in presence of nickel carbonate

showed that the latter did not interfere with the carbon estimation even if present to the extent of 40-50 times the weight of carbohydrate.

### Growth Curves of the Gramineæ

In my paper read at the Belgian Congress National des Sciences at Brussels in 1930, I gave a short account of my measurements of the growth-energy of *Triticum vulgare*, *Hordeum vulgare*, *Secale cereale* and *Avena sativa*, in accordance with growth (velocity) curves in general. I followed accurately each day at the same time, all shoots which issued from one single seed. The curves plotted on rectangular co-ordinates always gave a straight line between the points of inflexion (arithmetical series), and the Archimedes spirals constructed revealed for each kind of plant, during the whole of its life, two distinct growth-waves.

New experiments with the same and other Gramineæ have given the following results: the straight line between the points of inflexion is confirmed, the shoots are interdependent on one another and, in determined order, variable for each individual. For example, numbering the successive shoots of a given *Avena* type, shoot 2 issued from shoot 1, shoot 3 from shoot 2, 4 from 3, 5 from 4, 6 from 5, 7 from 3, 8 from 7, 9 from 6, 10 from 8, and so on, all 195 shoots finally being noted in a table of reference, with their order numbers, in two separate groups. The roots are in accordance with the corresponding grouping of the leaves, this being directly visible by careful carding of them. Plotting all curves of one sample of a complete individual on rectangular co-ordinates in chronological order, one sees, following the tops two or more distinct, regularly ascending-descending lines, that is, the pointed growth-waves of the above. From the beginning to the end they mark characteristic sines and cosines (tangents), and their distance apart again show successive agglomerations or groups from birth to death. A detailed account will be published later in *Roux' Archiv*.

### Esperanto in Scientific Literature.

FOLLOWING Mr Morris-Owen's letter in *NATURE* of Dec 5 regarding the use of Esperanto in scientific literature, readers who are interested, as I am, in meteorology, may like to know that, for several years the Aerological Laboratory of Tateno (Japan) has issued its yearly reports in Esperanto. These volumes containing on an average some 250 pages, 9 in. x 12 in. with many tables, diagrams, and maps, place at our disposal a wealth of information on local meteorological data, to which it was almost impossible for us to get access previously. This example was followed a couple of years ago by the Meteorological Office of the Trans-Siberian Railway, at Karbin: the translation into Esperanto is given by the side of the Russian text, which is a boon to the majority among us, who have found it much easier to master Esperanto than Russian. This year, the Institute of Meteorology and Geodynamics of Ljubljana (Yugoslavia) has followed suit, and I gather that similar institutions are considering taking the same step.

## Research Items.

**Ancient Gold and Enamel Work from Cyprus**—Mr L H Dudley Buxton describes in *Man* for January a remarkably fine piece of ancient gold and enamel work, found, it is said, with two bronze tripods and a fragment of a large bronze vessel by a peasant while digging at Episkopi, the ancient Curium. Unquestionably the bronzes were of Mykenæan age, but it is uncertain what reliance can be placed on the story that all the objects were found together. The object is 17cm in height and consists of a hollow cylinder of gold surmounted by a cloisonné sphere, on top of which stand two birds, almost certainly hawks. The cloisons on the sphere are formed by semi-circular bands in rows one above another. The colours are alternating rows of white, lilac, and green. The body feathers of the birds are similar but smaller scales, the wings and other large feathers are indicated by long parallel stripes. Mr Buxton's descriptive note is followed by a discussion of the dating by Mr S Casson. In default of positive evidence the period must be established by technique, colour, design, and style. The object has no parallel. The method of representing and distinguishing the feathers is derived from the East and first appears on Hittite sculpture in a modified form on the Sindhul sphinxes. It is not found in Egyptian goldwork, but it continues into Hellenic art, mostly in metal-work, and lasts into Byzantine times. The clue to the dating lies in the enamelled scales, which resemble very closely the incised coloured scales common on proto-Corinthian pottery. The application of enamel to cloisons in gold jewellery was not uncommon in the sixth, fifth, and fourth centuries B C, but this example seems the earliest known. It can scarcely be later than the sixth century B C and probably belongs to the early part of that century. Prof J L Myres adds a note in which he suggests the possibility of an earlier dating, pointing out the affinities of the treatment of the plumage and the wings, which exhibit features found in Phœnician, Hittite, and early Greek work. He recognises, however, that the earlier dating isolates the object as a piece of enamel technique. The object is figured in a coloured plate.

**Diorite Axes from Ireland**—Two remarkable diorite axes from Rathlin Island, Co Antrim, have been described by Dr Marcel Baudouin and Mr C Blake Whelan (*Bull Soc Préhist française*, 1931, No 10). Their peculiar character, which is of particular interest to French archæologists, lies in the fact that they differ from the 'diorite axes' found in Brittany and Vendée and resemble the Campignian 'flaked axes' of flint. One of them shows no signs of polishing, and may be compared with specimens of the middle Campignian, or Estrelhan, while the other is polished only at the base of the cutting edge, this bringing it into relation with the Jablmanian, the period of the introduction of polishing. The method of manufacture—by striking off large flakes—differs entirely from that of the polished flint axe, in the preparation of which a large number of very small flakes was struck off. It is evident that, like the Campignian axes of France, the Irish were made without any intention of subsequent polishing, and the size of the flakes is responsible for the irregular character of the work in the partly polished axe. It is to be noted that the fine grained diorite of Brittany and Vendée, unlike that of Ireland, is not suitable for flaking, but was worked by pecking, as is shown by incomplete specimens. It is evident that the two axes here under consideration come from the same workshop. The method of working is identical, except that the one which is partly polished has a number of fine retouches along the edges. The resemblance to the

'haches plates' in flint of the Paris basin is marked. It is concluded (1) that there are diorite axes which were worked by flaking, a fact not yet admitted in France, (2) that there are diorite axes of Campignian facies which are partly polished, and that in a manner differing from that found in France, and (3) that this technique required a special kind of diorite.

**Migration of Birds at St Kilda**—The first-fruits of an interesting natural history expedition to St Kilda carried out in the late summer of 1931, by T H Harrison and a party of enthusiastic undergraduates, appear in a short account of the early autumn migration of that year (*Scot Nat*, p 3, 1931). The visit lasted for three weeks, up to Aug 13, and the observers had the advantage of seeing the arrival of the forefront of the autumn migration, which had passed on before Dr Eagle Clarke landed on either of his prolonged visits. As a result, the composition of the migrant groups was somewhat different from that seen by Dr Clarke. The largest movements were those of waders, but, on the whole, there was a scarcity of those species which breed in high Arctic latitudes and apparently follow the natives of lower altitudes in migratory succession. Few of the migrants seen stayed more than a few days on the island. The list includes twenty-two species.

**Herring Behaviour**—In the *Journal du Conseil Permanent International pour l'Exploration de la Mer*, vol 6, No 2, 1931, Mr Michael Graham makes an original contribution to the study of the problems of herring behaviour. By collecting ideas from fishermen and observing at sea with the drifters, the author attempted to find out how and why the herring get into the nets. It is generally agreed that the entanglement of the fish in the net is due to some sudden concerted movement on the part of the shoals, known by the fishermen as a 'swim'. Mr Graham collected observations on the time, area, and directions of these swims. So far as information can show, the swims appear to be limited in area and to have a definite direction, that there are certain hours when the swims predominate seems certain. It is suggested that normally the herring can see the net, but that a shoal is subject to crowd psychology and will act concertedly under the influence of such factors as panic, sexual excitement, and migratory impulse; under such conditions the fish would be unable to avoid the net. The author records a number of fishermen's beliefs and discusses them in the light of his hypothesis. It is to be hoped that this very interesting work on the habits of the herring will be followed up.

**Storage and Transport of Fruit**—The Empire Marketing Board has recently published two reports on the deterioration of fruit during transit by sea. "Australian and New Zealand Fruit Shipments" (E M B No 46, H M Stationery Office, 1s net, pp 64, Nov 1931) is a report by the Economic Section of the Board of a five years' survey covering investigations in the Dominions and at the docks of Great Britain. Inquiry was directed along four main channels—over-ripeness, fungal rotting, internal breakdown, and bitter-pit. The first two causes of deterioration are aggravated by too high a temperature in the ship's hold. Two types of internal breakdown are described, one associated with low temperature and the other with late harvesting. Bitter-pit has been shown to be more extensive in early than in late picked apples, and more severe in fruit from trees bearing a light crop. The report emphasises the need for a uniform temperature during shipment, not too high to over-ripen or cause fungal

rotting, nor too low to cause deep scald or internal breakdown. The need for quicker handling of fruit consignments after arrival at British docks is also suggested. The other report is entitled "Transport and Storage of Bananas with special reference to Chilling", and is by Dr C W Wardlaw and Dr L P McGuire (E M B No 45, H M Stationery Office, 1s net, pp 37, Nov 1931). It deals chiefly with main stalk rot of bananas (*Thielaviopsis paradoxa*), finger stalk rot (*Gloeosporium musarum*), and fruit rot (*Botryodiplodia theobromæ*), and shows how these diseases can be overcome by rapid chilling of the cargo to 53° F. This temperature is low enough to curtail fungal activity and high enough to allow adequate ripening. Pre-storage and nutritional factors also influence the fungal rotting.

**Ensilage**—Ensilage has now become an important part of agricultural practice in the British Isles, and an up-to-date account of the subject is to be found in Bulletin No 37, issued by the Ministry of Agriculture as a revised edition of their Miscellaneous Publication, No 53 (London H M Stationery Office, price 1s), by A Amos and H E Woodman. Although the making of silage from succulent green fodders is recorded in 1843, the first attempts to introduce the art into Great Britain were but temporarily successful, and it was not until 1910 that any consistent advance in its production was made. The operation is not difficult, the crops are easy to grow, require less labour than roots, and can conveniently be cut between hay and corn harvests. In addition, silage has a high feeding value and will keep for a long period without deterioration. Several distinct forms of silage can be obtained according to the conditions under which it is produced, the quality can also largely be controlled. Although most herbaceous plants are satisfactory for conversion into silage, certain points should be observed in making a selection of the most suitable crop. The three chief methods of silage making are by means of tower silos, clamps, and stacks. Full details, including any necessary precautions, are supplied for each method. The chemistry of silage and the changes that occur in the plant while it is in the silo are also fully discussed, and a comparison of the results of feeding experiments with silage, the fresh green crop, and other commonly used food-stuffs shows that it can be used with advantage for many classes of stock.

**Ganometric Method of Measuring Geological Time**—Prof H Fairfield Osborn, with the assistance of Mr. E H Colbert, has published in the *Proceedings of the American Philosophical Society*, vol 70, No 2, 1931, a preliminary notice of a method of measuring time in its geological aspect. This method, which is termed the 'ganometric', has been arrived at from a close examination and comparison of the enamel folds in the posterior molar teeth of the many genera and species of elephants. It has been found that the total length of enamel, when measured along the folds, shows a definite increase in course of time. The rate of increase seems to vary in different phylogenetic lines, being rapid in some and slow in others. More detailed investigation into this interesting suggestion is in progress, and, if the thesis can be proved true, it will form a very useful test of the age of deposits and in addition will be most useful in helping to date such human remains and artefacts that may be found, as they sometimes are, in the same levels as proboscidean remains.

**A New Canadian Uraninite**—In 1930 uraninite was discovered in pegmatite on the Huron claim, Winnipeg River area, south-east Manitoba. Selected material has now been analysed by H V Ellsworth, and the results appear in the *American Mineralogist* for December 1931 with a general account in which

J S DeLury collaborates. The figures for age calculation are as follows

|                           |       |       |
|---------------------------|-------|-------|
| U                         | 53 50 | 55 01 |
| Th                        | 12 46 | 12 25 |
| Pb                        | 15 44 | 15 50 |
| Pb                        |       |       |
| $\bar{U} + 0.38 \bar{Th}$ | 0 265 | 0 260 |

The very high lead-ratio makes this the oldest uraninite yet discovered, and in view of this surprising result, it is of importance to notice that the authors add, "There is not the least suspicion that galena or any other foreign minerals were present." The ratio is approached only by that of the Ingersoll, South Dakota, uraninite (0.225) analysed by C W Davis. The Manitoba uraninite occurs in pegmatites that cut the Rice Lake series, which is lithologically similar to the Keewatin-Couchiching rocks of Ontario. If the age indication of the lead-ratio is accepted, the pegmatites must be very much older than those cutting the Grenville series in Ontario and Quebec, for which the corresponding ratios lie between 0.15 and 0.16.

**Measurements on Isotopes**—A number of new measurements on isotopes with the mass-spectrograph have been described by Dr F W Aston (*Proc Roy Soc*, Jan), which provide, as usual, a useful check upon the chemical values of the atomic weights. Caesium, for which the accepted chemical value is 132.81, has been found to have the distinctly higher atomic weight  $132.92 \pm 0.02$ . For strontium the positive ion value is  $87.64 \pm 0.06$ , in excellent agreement with the chemical value 87.63. For rubidium and thallium the chemical and electrical values are also in good agreement, although for the latter element Hönigschmid's number 204.39 is preferred to Briscoe's more recent 204.34. Barium ( $137.43 \pm 0.08$ ) also agrees reasonably well with the chemical determination, but for scandium Dr Aston's value is  $44.96 \pm 0.05$ , which is lower than the chemical value, 45.1, suggesting that the latter needs revision. For the remaining element studied, lithium, Dr Aston gives a value  $6.928 \pm 0.008$ , in good agreement with some other recent physical determinations, but not in accord with the results of band spectrum analysis.

**Ammonium Phosphomolybdate**—Although the yellow precipitate formed from molybdic and orthophosphoric acids in presence of nitric acid is known to have the composition  $(\text{NH}_4)_3\text{PO}_4 \cdot 12\text{MoO}_3 \cdot 2\text{HNO}_3 \cdot \text{H}_2\text{O}$ , it is usually supposed to be formed only when ammonium molybdate is present in large excess, and hence that the method cannot be used for the determination of molybdenum. Special conditions in great number have been published in connexion with the use of the method in the determination of phosphoric acid. Kitajima, in the *Scientific Papers of the Institute of Physical and Chemical Research, Tokyo*, No 330 (October 1931), shows that molybdenum can, in fact, be determined by this method, and he has worked out the conditions for the determination of phosphoric acid.

**Chlorination of Benzene and Toluene**—It is generally known that in the chlorination of toluene at higher temperatures substitution occurs mainly in the side chain, whilst in the presence of halogen carriers in the cold the nucleus is substituted. Mason, Smale, Thompson, and T S Wheeler have described (*J Chem Soc*, Dec 1931) experiments on the chlorination of toluene and benzene in the vapour phase, the main object being to determine to what extent chlorine enters the nucleus of toluene at high temperatures in the absence of specific chlorine carriers, and to determine whether, as regards the kinetics of side-chain chlorination, this hydrocarbon can be regarded as a substituted methane, the chlorination of the latter

hydrocarbon having been investigated by Mason and Wheeler, whose results were published in the September issue of the same journal. The results show that in the absence of specific carriers chlorine enters the side chain, and also, with the same conditions of short periods of heating, the kinetic formulae developed by Martin and Fuchs in 1931 apply to toluene considered as a substituted methane. In the case of benzene, the main object was to investigate, with particular reference to the formation of monochlorobenzene, the extent to which substitution occurs at high temperatures, in the absence of specific chlorine carriers. It is shown that direct chlorination to chlorobenzenes takes place in the vapour phase above  $400^{\circ}$ , mono- and di-chlorobenzenes being the chief products. The rate of reaction is not so great as in the case of toluene. The results, in the case mentioned, are in good agreement with the kinetic formula for a two-stage reaction. The rate of reaction is increased by addition of iodine, a chlorine carrier, and other liquid-phase catalysts. With ferric chloride the proportion of dichlorobenzene formed is increased and a little trichlorobenzene is also formed.

**Bushings for Outdoor Transformers**—The increasing use of outdoor substations for the transmission of electrical power has made it necessary to adapt transformers for use in unprotected positions out-of-doors. The transformers are usually connected to overhead transmission lines, the junction between transformer

winding and overhead line being at the terminals, where the winding is brought out from the oil tank surrounding the transformer. These terminals are called outdoor bushings, and on their design a great amount of scientific and mathematical research has been expended. In a paper read to the Institution of Electrical Engineers on Dec 3, Mr W J John gave a careful résumé of the work that has been done previously and deduced some useful conclusions. The main requirements of a bushing are that it must withstand all the electric stresses due to its connexion with the overhead system, insulate the conductors when rain is falling on the transformer, and be absolutely water-tight so that moisture cannot get into the insulating oil. Before the engineer accepts bushings, they have to pass certain standard tests, but the severity of these tests should not be unduly high. They have to be tested under artificial rain conditions, the water used having a standard resistivity usually of 10,000 ohms per cm cube. The shape of the bushings is of importance, so that the electric stresses which govern flash-over and puncture may be computed. It is of special importance to prevent the brush discharges, usually called the corona. Mr John gave laws for corona and puncture-voltage, and also for the permissible voltage gradients. He showed that for any given flash-over distance under wet conditions, the corresponding dry flash-over distance can be fixed within narrow limits, experiment shows that the law connecting the two is linear.

### Astronomical Topics.

**Astronomical Phenomena for February**—Venus is becoming increasingly conspicuous as an evening star, the planet is drawing away from the sun, and going farther to the north of it, its stellar magnitude is  $-3.5$ , three-quarters of the disc being illuminated. Venus will be near the moon on the evening of Feb 9, and about a degree north-west of Uranus on the evening of Feb 26.

Jupiter is in opposition on Feb 7, satellite II will be in transit from 1.15 to 4.7 A.M. on this day, and will partially cover its own shadow, reference should be made to the British Astronomical Association Handbook for mutual eclipses and occultations of the satellites, the seasons for these only occur once in six years, so opportunities should not be missed.

Neptune is in opposition on Feb 26, it is then  $1\frac{1}{2}^{\circ}$  east of the fourth magnitude star  $\rho$  Leonis which will make the planet easy to pick up in small telescopes.

Occultations of stars by the moon occur at 9.11 P.M. on Feb 11, at 7.35 P.M. on Feb 16, and at 6.19 P.M. on Feb 18, the stars are rather faint. February is a good month to look for the zodiacal light, since the ecliptic then makes its greatest slope to the horizon in the evening sky. This applies only to those who are far from the glare of artificial lights. The most convenient minima of Algol occur at 11 P.M. on Feb 16 and at 8 P.M. on Feb 19.

The well-known variable star Mira Ceti is due to reach its maximum early in April, but it will then be too near the sun for observation. It should, however, be visible to the naked eye after the middle of February, and it is of interest to follow the increase of its light, which is fairly rapid. Its position relatively to  $\alpha$  and  $\gamma$  Ceti and to  $\alpha$  Piscium should be learnt from a map. A binocular is a help.

**A New Faint Comet, 1931 e**—This comet was found by Herr K. Reimmuth on Dec 31 in the course of the regular work on minor planets that is carried on at Königstuhl, Heidelberg. It was of magnitude 15, its motion did not differ greatly from that of a minor planet, but both he and Dr M. Wolf decided that it was a comet after inspecting its images on four dif-

ferent plates, its aspect was decidedly nebulous, its diameter being estimated as  $36''$ . The following positions are from *Rechen-Institut's* Circulars 530 and 533, they are referred to the equinox of 1925.

|        |                                     |     |                                  |      |         |
|--------|-------------------------------------|-----|----------------------------------|------|---------|
| Dec 31 | 19 <sup>h</sup> 29 <sup>m</sup> U T | R A | 3 <sup>h</sup> 49 <sup>m</sup> N | Decl | 37° 26' |
| Jan 10 | 18 58.4                             |     | 3 45.1                           |      | 37 22   |
|        | 12 21 41.0                          |     | 3 44.7                           |      | 37 21   |

No orbit is yet to hand, but the above figures suggest that the comet was stationary in R.A. about Jan 16, in which case it would be near the discovery position at the end of January.

The comet was within a few degrees of 1931 d (Neujmin 1), but identity is not possible, the orbit of Neujmin being well known, moreover, it had sunk to magnitude 17 in December, and showed no sign of nebulousity at this apparition.

**Nova Pictoris**—A series of observations has been published (*Mon Not Roy Ast Soc*, Nov) of the components of this star made with the 26 $\frac{1}{2}$ -inch refractor at the Union Observatory, Johannesburg, by W H van den Bos and W S Finsen, they also include some made at Lembang, Java, by Dr J Voute. An interesting point is the outward movement of the components B, C from the principal star A. The measured distances early in 1928, 1929, 1930, and 1931 were for B  $0.35''$ ,  $0.55''$ ,  $0.84''$  and  $0.95''$ , for C they were  $0.38''$ ,  $0.60''$ ,  $0.80''$ , and  $0.98''$ . The faint component D remained nearly constant at  $0.27''$ , it was not visible in 1931. The nebulous and unsymmetrical character of the central nucleus A added to the difficulty of the measures, B and C faded more rapidly than A, in 1929 they were fainter than A by 1.6 and 2.1 mag, in 1931 by 2.6 and 3.6 mag. The paper compares Nova Pictoris with Eta Argus, it is recalled that Dr Innes detected two near companions of Eta Argus in 1914 and 1915, also the disc of the principal star appears nebulous in the 26 $\frac{1}{2}$ -inch. The light-curve of Eta Argus resembles that of a nova, differing only in the slowness of the changes, Nova Pictoris has also been slower than the average nova, but much more rapid than Eta Argus.

### The Kinematograph in Education.\*

AN account of what has been called "The Middlesex Experiment", carried out with sound films by a joint committee on which various educational authorities in the county were represented, has recently been published. The experiment was made possible by the generous offer of the Western Electric Company to provide, free of charge, sound film equipment and the services of competent operators. Sixteen films were used, divided into four groups, six had geographical value, four dealt with biology or nature study, and the other six were of general interest. These were lent by British Instructional Films and British Movietone News.

The value of the films to the children (3600, in fifteen schools) was tested in the first instance by questions set on each film, easier questions in some cases for the junior pupils and more difficult questions for the senior pupils, with an essay in special cases. A questionnaire on the value of each film was answered by a teacher in each school. Final conclusions were drawn from an examination of these sources of information, control classes taught in the usual way without films being considered too cumbersome.

It may be said at once that, if the opinions of teachers are worth anything, a case is made out for the use of films in educational work in schools. There is, indeed, plenty of criticism, one of the facts that emerged is that even the best film material available for use in schools is unsatisfactory in numerous respects. But it is also stated that "even the least satisfactory among the films used in the experiment had a certain value as instruments of education, the better films were frequently stated to be of very considerable value". The films created a liveliness of mind and desire for further learning that is not taken account of in any assessment of answers to questions on the scenes exhibited.

It is curious, however, that while the title of the volume is "Sound Films in Schools", and while, in fact, sound films were used, the emphasis seems to be laid not so much on the sound film as compared with the silent film or with the ordinary lesson, but on results of using the sound film with pupils of different grades of intelligence. We are not impressed by the evidence that the sound film is "superior" to the silent film. There is, indeed, the statement that "the

\* Sound Films in Schools: the Report of an Experiment undertaken jointly by certain Local Education Authorities and by the National Union of Teachers in the Schools of Middlesex. Pp viii+120+8 plates. (London: The Schoolmaster Publishing Co., n.d.) Cloth, 2s 6d, paper, 1s 6d.

general consensus of opinion on the part of teachers consulted is that they [the sound films] are preferable to silent films for educational purposes", but the statement comes as a shock to the reader. Practically no evidence, statistical or other, is adduced to support the statement in this extreme form. So far as can be gathered, there were no control experiments with adequately captioned films, and it is certainly interesting to note that one of the most common criticisms of the films was that there were too few captions.

On the other hand, there are many solid results of the investigation and suggestions for further inquiry. The children were divided into those of average ability and those described as backward, and probably the most striking result of the experiment was the value of the film to the backward pupils, it is, indeed, in the case of the backward pupils that the value of the sound film is most clearly demonstrated. Another very striking result, though it is rather belittled in the text, is that the lesson should follow the film—not precede it. The evidence for this (as given in Table XVIII) is overwhelming. The result is as important as it is striking. It implies that, under the conditions of the experiment, the picture was *not* an illustration but the raw material.

The experiment, in fact, marks another advance in our knowledge of how to use films in school. The criticisms of teachers have led to the formulation of definite requirements that such films must fulfil. The committee of the Geographical Association, which has been investigating silent films, has come to almost identical conclusions. It may, therefore, be taken for granted that all school teaching films, sound or silent, must have the following qualifications:

- (1) The film must be coherently planned
- (2) It should be short and aim at conveying one main idea
- (3) All essentials to the main theme must be included and irrelevances ruthlessly excluded
- (4) The commentary should be in simple language and should anticipate the picture
- (5) Talking down and cheaply humorous touches must be avoided
- (6) The repetition of essential action is recommended
- (7) Films should be correlated with recognised courses of study
- (8) Only such subjects should be shown in film form as cannot be more effectively dealt with through another medium

### Pit-Dwellings in Arizona.

FOR several seasons past Dr Frank H. H. Roberts, Jr., has been engaged on behalf of the Bureau of American Ethnology, Smithsonian Institution, Washington, D.C., in the investigation of archaeological sites in Arizona and Colorado, with the view of tracing the development of the culture of the 'Basketmakers', the prehistoric inhabitants of the arid areas of the south-western United States, and its relation to that of the early Pueblo Indians. The following is a report of the field-work in the summer of 1931, which has revealed what would appear to be a hitherto unsuspected phase in the development of the multi-cellular dwelling characteristic of later Pueblo culture.

During the summer field season of 1931 investigations were carried out at a site three and a half miles south of Allantown, Arizona. When the work

was brought to a close at the end of September the subterranean portions of fourteen pit-houses had been cleared of the debris which accumulated in them during the centuries which have passed since their abandonment. Several of the dwellings had been destroyed by fire, and the charred remnants of timbers lying on the floors demonstrated clearly the methods of roof construction. This evidence, together with the nature of the pits which remain, makes possible the drawing of an accurate picture of the type of dwelling in vogue during the early stages in the occupation of the site.

The semi-subterranean houses were rather crude. They had consisted of a circular, oval, or rectangular excavation roofed over with a pole, brush, bark, and plaster superstructure. The earth walls of the pits were covered with plaster made from adobe mud in

which there was a small admixture of ashes. The pits ranged from 0.91440 m to 1.524 m in depth and from 3.048 m to 6.096 m in diameter. The superstructure erected over the pits was supported by four upright posts set in the floor a short distance from the walls. The upper ends of these main supports were forked, tree trunks with suitable crotches having been obtained for the purpose, and carried crossbeams. These stringers formed a rectangular framework against which were placed the upper ends of smaller timbers, the butts of which rested on the ground some distance back from the edges of the pit. The slanting poles formed the main part of the sloping upper walls of the house. At the top the rectangular space was covered with a flat roof, with an opening near the centre which functioned as a smoke-hole and entrance. The entire framework was covered with brush, leaves, and strips of cedar bark. On top of this a thick layer of mud plaster was spread, and over all there was a thin coating of earth. Indications were that the tops of the roofs were only elevated above the ground sufficiently to provide for drainage. A village composed of houses of this type would not be striking in appearance, since all that an onlooker would see would be a series of low, rounded mounds with the ends of ladders projecting through rectangular openings in their tops.

The interior features of such houses were simple. Near the centre of each, directly under the opening in the roof, was a fire pit. Close to it, on the south-east side, was a second depression in the floor, in which rested the lower end of the ladder used in gaining access to the chamber. An occasional dwelling had a storage recess in the wall. Where these were present they were on the floor level, none was placed above it. At the east or south-east side of each room there was an aperture in the wall, which opened into a short tunnel. The latter led to a vertical shaft the outlet of which was on the ground-level some distance from the edge of the roof mound. This constituted the ventilator. The nature of the houses was such that a constant supply of fresh, cold air was drawn down into them through this ventilator. Between the opening in the wall and the fire pit, at the base of the ladder, an upright slab of stone was set in the floor. This is called the deflector, and was so placed to pre-

vent the rushing air from blowing directly on the fire. The draft at times was so strong that it was necessary to stop completely the opening. A well-worked oval slab of stone was provided for this purpose. The cover stones were found in position over the opening in a number of the pits when they were excavated.

Houses of the type just described generally stood alone, but in two different groups at this site they were connected. There were no partitions at the sides where they joined, and long, narrow dwellings resulted. One of the examples was composed of two and the other had three connecting chambers. Each room was complete in itself, to the minutest detail, but because of the lack of a separating wall, became an integral part of the larger structure. It is possible that the two groups represent one of the prototypes for the communal dwellings which in later times were erected above ground. If such were the case, there is in this distinct evidence of an interesting variation in the evolution of the house. In the more northern parts of the south-west archaeological area, the single family domiciles had practically emerged from the ground before the development of the multiple-roomed structures began. In general it may be said that the structures uncovered in 1931 conformed to the widespread semi-subterranean type of house built in many sections of the south-west. They are particularly comparable to the pit-dwellings which Dr. Roberts found during previous investigations in the Chaco Canyon, in north-western New Mexico, and at the old Long H Ranch, Arizona, about 48.280 km south and west of the Allantown location. All showed individual differences and variations, but in their main essentials they exhibited a striking similarity.

The Allantown site is of considerable importance, because trenching has shown that it contains four distinct and sequent levels of occupation. Complete excavation will throw light on the closing days of the Basketmakers, show the beginnings of the Pueblo culture, and trace its growth through two subsequent periods. The houses excavated in 1931 belong to the Pueblo I phase. Investigations will be resumed in the present year, when further portions of the site will be cleared.

### Fuel Research in Great Britain.\*

THE Report of the Director of Fuel Research for the year ending March 31, 1931, has only recently been issued. The delay in publication, usual with official documents, detracts somewhat from the freshness of its contents, for in recent months, at the centenary meeting of the British Association and other gatherings, the status of fuel processes has been the subject of repeated discussion.

There is a discussion by the Director of the economic status and prospects of the evergreen topic of low-temperature carbonisation of coal. He expresses the opinion that the receipt from the coke will have at least to cover the cost of the coal carbonised. The coke must fetch more per ton than the coal from which it is made. The crux of the question is the price which the nation is prepared to pay for the reduction of smoke nuisance, while at the same time retaining the open domestic fire. The damage and expense incurred by burning a ton of raw coal in the domestic hearth has been calculated to be 10s., and if this sum could be included in the balance-sheet there is little doubt that the production of free-burning

cokes would soon become a flourishing industry. It must be remembered that gas and ordinary gas-works coke are both smokeless fuels, the uses of which are extending, as is the use of electricity for many domestic purposes. Indeed, the rapidly growing use of gas coke as a fuel for open grates of suitable design is a factor which should not be overlooked.

The Report states that the benefit to the mining industry would be less than frequently claimed, because the use of carbonised fuel would merely displace house coal, the demand for which would be correspondingly reduced. The fall in the value of liquid fuels which has occurred in recent times places a great obstacle in the way of new carbonisation industries, and also of the production of oils by the direct hydrogenation of coal.

Low-temperature tars regarded as fuel oils or 'cracking stock' have defects. On the other hand, they appear to lend themselves to conversion into stable oils and motor spirits by hydrogenation. The Report gives the results of encouraging experiments in this direction, and it seems that the hydrogenation of tar may advance more rapidly than the direct hydrogenation of coal.

The Report reviews the circumstances in which the

\* Department of Scientific and Industrial Research. Report of the Fuel Research Board for the year ended 31st March 1931 with Report of the Director of Fuel Research. Pp viii + 104 + 2 plates. (London: H.M. Stationery Office, 1931.) 2s. net.

Gas Light and Coke Company came to select the low-temperature carbonisation system developed at the Fuel Research Station for a full scale commercial trial at the Richmond Gas Works. Various causes led to the cessation of the experiments before, in the opinion of the Department and the Mines Department, a conclusive result was obtained. One of the principal difficulties encountered was the distortion of the metal retorts employed. This distortion resulted in an unduly heavy charge for replacements being added to the cost of the working of the plant. In view of the very promising results and increased throughput recently obtained at the Fuel Research Station with a brick retort, it is proposed to erect and work as steadily as possible two new retorts of that type at the station, so as to obtain further data regarding the life and working of such retorts. The disappointing results of this attempt to develop an apparently promising low-temperature process illustrate the need for caution in forecasting the commercial prospects of new schemes in this field.

Very interesting results have been obtained with horizontal gas retorts. By modifying the method of heating the retorts, the daily throughput has been increased by 70 per cent. The effect of this on the economics of carbonisation may be far-reaching, for more than seven million tons of coal are carbonised daily in such plant.

The organisation of the Physical and Chemical Survey of the National Coal Resources has now been almost completed, and covers practically all the coal areas in the country.

Many other aspects of the national fuel problems are touched in this interesting report.

### Treatment of Fodder Crops.

VARIOUS are the proposals for restoring arable farming to its former prosperous state. Apart from the recent Government promise of establishing a quota for wheat, we have had such interesting suggestions as Prof. Orwin's mechanised farming, which is already being tried in various parts of the country, and the erection of canning factories in which fruit and vegetables take the place of wheat, and of which two are already being built in Norfolk alone. Yet a third proposal which seems worthy of trial is the so-called 'Mason System for Harvesting and Drying Green Fodder Crops'. The process invented by Mr. Arthur J. Mason is the result of twenty years' experimental work, and has been in commercial operation in the United States since 1926. It aims at producing home-grown feeding stuffs by artificially drying green fodder crops cut before the flowering stage and converting them directly into high-grade feeding-stuffs of comparable value with such imported products as cake, cereals, wheat offals, etc., at a distinctly lower price. The Rothamsted Experimental Station is already running some eighty experimental plots with the view of discovering the most suitable crops in Great Britain for the Mason process.

Investigations seem to show that crops thus grown in place of cereals will increase the yield of English arable lands about three and a half times (in food and monetary value) and assure the farmer a net profit of £2-£5 an acre, provided that the crop is cut three or four times in the season—a perfectly feasible matter if the crop is cut before flowering sets in. In such cases the normal yield per acre is, compared in feeding value with cereals, 3 to 4 tons per acre against 0.8 tons of wheat, the value of the product being  $3\frac{1}{2}$  times as high. The system has the further advantage of completely eliminating the more or less

considerable loss in hay-making caused at present by the ordinary vagaries of the English climate. The crop, in fact, can be cut at any time, regardless of the weather, and the feeding value of the product is approximately double that of the ordinary sun-dried hay, there being no loss of proteins or vitamins by 'wilting' in the sun or by exposure to wet. This, with lucerne, which yields in the case of ordinary hay-making about 12 per cent protein, the content of protein rises to 18 or 20 per cent when treated by the Mason process.

The installation costs approximately £7600, allowing £3500 for the drying plant and the rest for harvesting and haulage. It is capable of dealing with the product of 800 to 1000 acres, and should produce about 2600 tons of concentrates, worth £15,600 to £20,000, per annum, which could be grown within a three-mile radius in any arable district. Each factory could be organised as a single operating company, which purchases the standing crops and carries out the harvesting and the drying, the farmer receiving £2 per ton (dry) for his crops. Obviously in view of the farmers' sad experience with the sugar beet factories, the farmers concerned should have a direct interest in the factory and some say in the prices. The factories would first concentrate on the production of fine ground meal for poultry food, for which there is an immediate market, but the product has also been found invaluable for cattle and sheep feeding. Considering the costliness of erecting sugar-beet factories and the large amount of the sugar-beet subsidy, it would be quite worth while for the Ministry of Agriculture to consider if some of the subsidy might not be diverted to encouraging the erection of some of these factories, of which the cost appears extremely modest. The system was recently brought to the notice of Section M (Agriculture) of the British Association by Sir Richard Paget, Bt. (1 Devonshire Terrace, London W.2), from whom further information can be obtained.

### University and Educational Intelligence.

CAMBRIDGE—A. S. Paterson has been appointed to the Pinsent-Darwin studentship for three years from Oct. 1.

The council of the Senate has issued a report on accommodation for the Department of Mineralogy and Petrology. It is recommended that a new building covering about 5600 sq. ft. and containing four floors should be constructed between the Sedgwick Museum and the Department of Physiology.

At Emmanuel College, Mr. F. T. Brooks, University reader in mycology, has been elected to a reserve official fellowship.

LONDON—At a meeting of convocation on Jan. 1 the Earl of Athlone was elected chancellor of the University. The installation ceremony will be held at the University on Feb. 18.

The following degrees have recently been conferred: D.Sc. (Statistics and Eugenics) on Ethe Mary Elderton (University College) for "Report on the English Birthrate" (*Eug. Lab. Publications*, 1914) and "On the Factors which influence Infant Welfare" (*Annals of Eug.*, 1926-29); D.Sc. (Economics) on Hilda Rodwell Ormsby (London School of Economics) for "The Geography of France—Regional and Economic" (Methuen, 1931).

The following titles have been conferred in respect of posts held at the Colleges indicated: Professor Dr. Robert Robinson (biochemistry, Lister Institute of Preventive Medicine); Reader Dr. J. M.

Gulland (biochemistry, Lister Institute of Preventive Medicine), Dr William Robson (biochemistry, King's College), Dr Edward Mallett (electrical engineering, Imperial College—City and Guilds College), Mr Albert Rushton (electrical engineering, Imperial College—City and Guilds College), Dr G I Finch (general chemical technology, Imperial College—Royal College of Science), Mr V C Illing (geology—petroleum technology, Imperial College—Royal School of Mines), Dr A Morley Davies (palaeontology, Imperial College—Royal College of Science)

NOTTINGHAM—The Massey scientific research fellowship, of the value of £400 per annum, which has recently been established at University College, Nottingham, for the purpose of promoting research on cancer by physical and chemical methods, has been awarded to Dr L A Woodward. After two years' research under Dr N V Sidgwick at Oxford, Dr Woodward was awarded a senior grant by the Department of Scientific and Industrial Research to carry on, under Prof P Debye, spectrophotometric research on the Raman effect in electrolytes

APPLICATIONS are invited for Tate, Morgan, and Holl scholarships at the Battersea Polytechnic. The scholarships range in value from £20 to £30 per annum with free tuition and are tenable for two or three years. Particulars are to be had from the Principal, Battersea Polytechnic, SW 11. The last day of entry is April 16.

At a dinner, on Jan. 18, given by the Argentine Chamber of Commerce in Great Britain, the Prince of Wales announced the provision of scholarships at the University of Oxford, on the lines of the Rhodes scholarships, to enable students from the University of Buenos Aires to study in Great Britain. So far, provision has been made for two students from the University of Buenos Aires to go to the University of Oxford for a period of two years.

THE subject for the essay for the Cecil Peace Prize of £100, which is offered annually for an essay on some topic connected with the maintenance of international peace, has been announced. For the year 1932, the subject is "The Danger from the Air. Discuss possible methods, by International Convention or otherwise, of dealing with it." Further particulars can be obtained on application to the Secretary, Universities Bureau of the British Empire, 38A Gower Street, London, WC 1.

### Calendar of Geographical Exploration.

Feb. 3, 1488—The Cape of Good Hope

Bartholomew Diaz de Novaes touched the south coast of Cape Colony at Mossel Bay (Bahia dos Aqueros), midway between the Cape of Good Hope and Port Elizabeth. Diaz sailed from Lisbon for the Congo river in 1487 and thence surveyed the coast of Africa southwards to Walfish Bay. The currents off the South African coast hampered him, and he sailed far to the south of the Cape of Good Hope into the region of the westerlies, but finally reached the coast on the above date. Thence he proceeded to the mouth of the Great Fish river, but the discontent of the officers and men compelled him to return. In December 1488 he was back in Lisbon. His voyage opened the way for the route round Africa to the east, and added 1260 miles of coast-line to the map of Africa. Fragments of the pillar which he erected on Diaz

Point in 26° 38' S. (South-West Africa) still remain. Diaz accompanied Cabral on his voyage in 1500, when Brazil was discovered, and should have helped to guide the fleet thence to India, but perished in a great storm off the Cape of Good Hope.

Feb. 3, 1643—Japan and Sakhalin

Martin Gerritszoon Vries sailed with two ships from Batavia in search of imaginary islands, one supposed to be rich in gold and one in silver. The ships were nearly wrecked off Nippon, but reached Yezo and discovered an island, probably Iturup, passing through the strait which still bears the name of Vries. Part of the coast of Sakhalin was then explored, and descriptions of the hairy Ainu were brought back. The companion ship, instead of sailing through Vries Strait, passed along the outer shores of the Kurile Islands, reaching 47° 8' N, twelve degrees east from the most easterly point of Nippon.

Feb. 4, 1823—Lake Chad.

Lake Chad was seen by Europeans for the first time. Denham, Clapperton, and Oudney had set out from Tripoli in the hope of gaining further knowledge of the Niger. The party crossed the Sahara, reached Bornu, explored Lake Chad, and proved that the Niger was in no way connected with it. They brought back accounts of the Arabs, the Berbers, the Fulah, and of many negro tribes. The information thus collected about the kingdoms of the Central Sudan threw much light on the writings of Arab travellers.

Feb. 5, 1725.—Bering's Voyages.

Vitus Jonassen Bering set out from St Petersburg to conduct an expedition to north-east Siberia in order to find whether Asia and America were separate. Peter the Great had appointed Bering to be commander, but in 1724 Peter died before the preparations were completed. Bering and his companions crossed Siberia by land, going from stream to stream and carrying with them the materials for the boats, which were built in Kamchatka. Bering sailed north-eastwards along the coast of Kamchatka, surveying it as he went. On Aug. 15, 1728, he sailed past the north-eastern promontory of Asia in 67° 18' and observed that the coast trends westwards, as the Chukchee had already told him. He considered that he had thus fulfilled his mission and returned to Kamchatka, whence he tried to reach America, but was driven back by bad weather conditions.

In 1740, Bering fitted out two vessels at Okhotsk, the *St. Paul* and *St. Peter*, the latter being commanded by Chirikov, and they set out for America. During a storm the vessels separated. Bering reached America between lat. 58° and 59° N, where the naturalist, Steller, who was with him, noted the volcano, Mount St. Elias. With great difficulty owing to continuous fog, the *St. Paul* rounded the peninsula of Alaska. Scurvy broke out among the crew, and the ship drifted helplessly at the mercy of wind and wave among the Aleutian Islands. It finally ran aground on Bering Island, where Bering died on Dec. 8. Thirty-two out of a party of seventy-six had died, but the survivors built a new vessel, and ultimately reached Kamchatka. Steller wrote a full account of the six months' stay on an uninhabited island, giving a valuable description of the fauna. Chirikov also reached the coast of America, in lat. 56° N. Bering's voyages decided the question of the existence of a strait between North Asia and North America. The strait had been passed by Dezhnev eighty years before, but no record had been kept of this. Bering's and Chirikov's voyages brought to light the existence of the long chain of volcanic islands between Alaska and Kamchatka.

## Societies and Academies.

## LONDON.

Royal Society, Jan 21 — C Donhoff and J J. R. Macleod Studies in the nervous control of carbohydrate metabolism When decerebration is performed through the pons in rabbits under amytal anaesthesia, the percentage of blood sugar rises very high after the effects of the anaesthetic have passed off After pontine decerebration the percentage of lactic acid increases in the blood and the percentage of glycogen decreases in the muscles, but may either increase or decrease in the liver No relationship exists between the degree of decerebration, hyperglycaemia, and the percentage of glycogen initially present in liver and muscles, and when previously fasted animals are used it is impossible to account for the hyperglycaemia by the sugar arising from the glycogen which disappears. It is concluded that a process of gluconogenesis is responsible for most of the extra sugar, but it has so far proved impossible to determine the extent to which protein and fat contribute towards its production. In fasted animals, having small percentages of glycogen in the liver and muscles, pontine decerebration fails to induce hyperglycaemia after double adrenalectomy, or administration of atropine, ergotamine, or amytal It is concluded that decerebration hyperglycaemia is in large part due to stimulation through the autonomic nerves of some process by which the liver discharges sugar in excess of that available from the glycogen initially present in it Since amytal paralyses this pathway, it prevents the rise in blood sugar percentage following pontine decerebration, piqûre, and asphyxia, but not that due to the injection of large doses of adrenaline — W T Astbury, T C Marwick, and J D Bernal X-ray analysis of the structure of the wall of *Valonia ventricosa* (1) The cell-wall is built up of two main sets of cellulose chains which form crystallites crossing at an angle maintained remarkably constant through the whole thickness and over considerable areas of the wall The orientations of the cellulose chains are parallel to the directions of the fine crossed striations which may be detected on the surface of the wall The extinction directions shown by the wall in polarised light lie between the directions of the cellulose chains and vary in a manner determined by the inter-chain angle and the relative proportions of the chains associated with each orientation — F A Askew, R B Bourdillon, H M Bruce, R K Callow, J St L Philpot, and T A Webster Crystalline vitamin D Further purification of the antirachitic principle has been achieved by esterification of the crystalline distillation products formerly described as calciferol The purified calciferol now obtained has an antirachitic activity twice as great as any previously recorded, and appears to be identical with the vitamin D<sub>2</sub> of Linsert and Windaus A simplified process is described for preparing the pure product from the irradiation products of ergosterol without distillation An account is given of two inactive compounds termed pyrocalciferol and sterol X Evidence is given of the relations between the crystalline antirachitic products hitherto described, showing that the activity of each of them is due to one common constituent Thus the vitamin D<sub>1</sub> of Windaus is a compound of calciferol (=vitamin D<sub>2</sub>) and sterol X, and the crystalline distillation products first described contained pyrocalciferol and sterol X, as well as calciferol (See also NATURE of Oct 31, 1931, p 758, and Jan 9, p 50)

Academy of Sciences, Dec 21 — A. Lacroix The members and correspondents of the Académie royale des Sciences (1666–1793) — Paul Pascal and Pierre Minne The existence and preparation of lead suboxide The only method of preparation giving a definite compound is the decomposition of lead oxalate at 275°C in a vacuum (1 mm) The magnetic susceptibility proves that it does not consist of the mixture Pb+PbO The pure suboxide (Pb<sub>2</sub>O) cannot be obtained by the reduction of lead monoxide — Lucien Lichtenbaum A topological invariant — E Pinte Congruences of straight lines and parallel surfaces in Hilbertian space — Jacques Networks the tangents of which belong to linear complexes and non-Euclidian surfaces of constant total curvature — Paul Mentré The projective application of a quadratic complex on the non-special linear complex — F Marty The iteration of certain algebraic functions — M Davin The elastic state of an indefinite two-dimensional body pierced by a circular hole — D Belorizky The application of Sundman's methods to the problems of celestial mechanics — A Lallemand The preparation of two types of aqueous solutions of cobaltous salts Study of their magnetic state as a function of the dilution Two types of solutions of cobalt salts are known, in the first the magnetic susceptibility is constant and independent of the concentration, in the second the magnetic susceptibility increases with dilution to a sharp maximum The author gives the conditions for preparing either of these types of solution at will — L Neel The magnetic properties of iron above the Curie point From studies of the magnetic properties of iron-tin alloys and iron-silicon alloys at temperatures ranging from 800°C to 1100°C, the ferromagnetic Curie point found ( $\theta_f$ ) is 772°C, and the paramagnetic Curie point ( $\theta_p$ ) is 815°C — Mile. A Serres The magnetic moment of tetravalent cobalt From a study of magnesium cobaltite (MgO CoO<sub>2</sub>), the magnetic moment of Co<sup>+++</sup> is found to be 29.0 magnetons — E Rinck An allotropic transformation of barium in the solid state Barium, fractionally redistilled in a vacuum, is attacked by carbon dioxide and can only be handled in argon Its melting point was redetermined and found to be 710°C From a study of the electrical resistance two allotropic forms of barium are shown to exist  $\alpha$ -barium stable below 375°C. and  $\beta$ -barium stable between 375° and 710° C — Mion Contribution to the study of the system water, ethyl alcohol, acetic acid, ethyl acetate The miscibilities of the ternary system (water, alcohol, ethyl acetate) and quaternary system have been determined at 0°, 15°, and 30° C the results are given in tabular form — M Bourgue and L Piaux The Raman effect and chemistry the allene linkages The Raman effect for allene and its derivatives shows that these hydrocarbons contain neither an ethylene nor acetylene linkage Hence the usually accepted formulae require revision — Jean Cournot The influence of the state of the surface on the corrosion of rustless steels The effect of the condition of the surface on corrosion is specially marked in the case of rustless steels to obtain maximum resistance to corrosion it is necessary to polish the surface with the finest grade emery — Mile Suzanne Veil Precipitations stratified in spirals — M Patry and P Lafitte The beginning of the explosive wave in mercury fulminate — Frank A Perret The new dome of Mt Pelée — Emile F Terroine and H Trimbach The urinary excretion of ketonic substances during starvation in various species of animals Experiments on the pig, rabbit, dog, cat, and rat showed no increase in ketonic sub

stances excreted in the urine during starvation, on the contrary, there was a reduction. The increase observed in man and in the primates appears to be exceptional.—J Errera. The electrometric titration of the proteins. The isoelectric points of the albumins and globulins are in the acid region ( $pH$  4–5.5), whilst those of the prolamines and glutelins are in the alkaline region ( $pH$  8–10).—Paul Fleury. The glycerophosphomolybdates. In the glycerophosphates the phosphoric acid still possesses, although in a weakened form, the property of forming complex compounds with molybdic acid. Two of these have been isolated in the crystalline condition, sodium  $\beta$ -glycerophosphomolybdate and potassium  $\beta$ -glycerophosphomolybdate.—A Ch Hollande and Mme G. Hollande. The cytology of *B. coli*.

## SYDNEY.

Royal Society of New South Wales, Nov. 4.—A R Penfold. The essential oil of *Leptospermum Liver- sidgii* var B and the occurrence of isopulegol. The presence of *d*- $\alpha$ -pinene, citronellal (33.42 per cent), and sesquiterpene alcohol was confirmed, and the occurrence of isopulegol both free and combined as caprylic acid ester revealed. The isolation and identification of this alcohol is the first authentic record of its occurrence in Nature.—E. Cheel. Notes on the *Pericalymna* section of the genus *Leptospermum*, with descriptions of three new species. An account was given of the first collection of plants commonly known as 'tea-tree' in Australia or 'manuka' in New Zealand, made by John Reinhold Forster and his son, George Forster, who accompanied Capt Furneaux of the *Adventure*, which left England in 1772, on Capt Cook's second voyage to the shores of Australia. Three new species were described. *L. trivalvum* has small capsules, normally three-valved. The plant otherwise resembles *L. myrsinoides*, which is confined to Victoria, whereas the new species is widespread over the western and southern parts of New South Wales, extending to Victoria. *L. sphaeocarpum* has spherical-shaped fruits, and has affinities with *L. nudum*, a Tasmanian species. *L. semibaccatum* has fruits somewhat berry-like when fresh, an unusual character for this group of tea-trees.

## VIENNA.

Academy of Sciences, Oct 15.—A Kailan and J Kohberger. The velocity of catalysed hydration.—L Moser and H Hackhofer. The determination and separation of rare metals from other metals. (20) The determination of iridium and its separation from platinum and other metals. Hydrolysis was used and also bromide-bromate.—L Moser and H Graber. The determination and separation of rare metals from other metals. (21) The determination of rhodium and its separation from platinum and other metals. Oxidising hydrolysis was in many cases successful.—W J Muller, H K Cameron, and W Machu. The theory of passivity phenomena. (14) The passivity of nickel. The substances forming surface layers are the natural nickel oxide which forms in air, basic nickel sulphate, double refracting nickel sulphate pentahydrate, nickel peroxide.—J Kuhntrieber. New Plecoptera larvæ.—F J Widder. *Draba norica*, a new plant of the Eastern Alps.—A Rollett and F Scholz. The course of esterification with mixed anhydrides and mixtures of anhydrides.—M Mladenovic. The elemic acid from *Manila elemi* resin. (3) The elemic acid, its hydration product, and bromo-hydro-elemic acid.—A Dadiou, K W F. Kohlrausch, and A Pongratz. Studies on the Raman effect. (16) The Raman spectrum of organic substances (cis-trans-isomerism).—A Dadiou and F A Schneider. Raman effect and constitution of nickel carbonyl.—S Pelz. Electrolytic coloration of alkali halide crystals.

## Forthcoming Events.

## Societies.

## FRIDAY, JANUARY 29

SOCIETY OF MEDICAL OFFICERS OF HEALTH (Fever Hospital Medical Service Group) (at 1 Upper Montague Street, W C 1), at 4.—Dr E W Goodall, Pre-bacterial Views of Infectious Diseases (Presidential Address). ROYAL ASTRONOMICAL SOCIETY (Geophysical Meeting), at 5.—Prof E V Appleton. Upper Air Ionisation. ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Sir Arthur Keith. Malformations of the Human Body considered from a New Point of View (Hunterian Lecture).

## MONDAY, FEBRUARY 1

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof J P Hosford. Some Factors in the Causation of Hydronephrosis (Hunterian Lecture). ROYAL INSTITUTION OF GREAT BRITAIN, at 5.—General Meeting. SOCIETY OF ENGINEERS (at Geological Society) (Inaugural Meeting for Year), at 6.—F W Mackenzie Skues. Presidential Address. INSTITUTE OF FUEL (at Institution of Electrical Engineers), at 6.30.—Presentation of the Melchett Medal to Prof. Bone and delivery of the Melchett Lecture by Prof Bone. A Century of Fuel Economy. ROYAL SOCIETY OF ARTS, at 8.—Capt O A Barrand and G A Green. Life-Saving Appliances on Merchant Ships (Thomas Gray Lectures) (3).

## TUESDAY, FEBRUARY 2

ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof C A Edwards. The Progress of Research relating to Physical Metallurgy (3).

## WEDNESDAY, FEBRUARY 3

ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof R T Payne. Excretion Urography (Intravenous Pyelography) (Hunterian Lecture). ROYAL SOCIETY OF ARTS, at 8.—A Broughton Edge. Geophysical Methods of Prospecting. ROYAL SOCIETY OF MEDICINE (Medicine and Surgery Sections), at 8.30.—Special Discussion on Diagnosis and Treatment of Abscess of the Lung.

## THURSDAY, FEBRUARY 4

LONDON MATHEMATICAL SOCIETY (at Royal Astronomical Society), at 5.—M H A Newman. Topological Methods in the Theory of Continuous Groups (Lecture). ROYAL INSTITUTION OF GREAT BRITAIN, at 5.15.—Prof H G Cannon. Feeding and Digestion of Invertebrates (3).

## FRIDAY, FEBRUARY 5

ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5.—Discussion on Common Colds and their Sequelæ. ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5.—Prof. A R Hobbs. Puerperal Sepsis, with an Account of the Treatment of Puerperal Infection by Glycerine Drainage (Hunterian Lecture). GEOLOGISTS' ASSOCIATION (in Botany Theatre, University College) (Annual General Meeting), at 7.30.—Prof W W Watts. Fossil Landscapes (Presidential Address), and presentation of Foulerton Awards to F Gossling and Dr S W Wooldridge. ROYAL INSTITUTION OF GREAT BRITAIN, at 9.—Dr G C Simpson. Weather Forecasting.

## Public Lectures

## FRIDAY, JANUARY 29

IMPERIAL COLLEGE OF SCIENCE (Royal College of Science), at 5.30.—Dr T M Finlay. The Evolution of Landscape. The Desert (Swiney Lectures) (11).

## SATURDAY, JANUARY 30

HORNIMAN MUSEUM (Forest Hill), at 3.30.—Dr A I Richards. Women's Life and Work in a Central African Tribe.

## MONDAY, FEBRUARY 1

- LONDON SCHOOL OF ECONOMICS, at 5—H D Henderson Trade Theories and the Great Depression (1) (Succeeding Lectures on Feb 8, 15, and 22)
- GUY'S HOSPITAL MEDICAL SCHOOL (in Physiological Theatre), at 5—Prof H A Harris The Use of X-Rays in Physiological Investigations
- IMPERIAL COLLEGE OF SCIENCE (Royal College of Science), at 5 30—Dr T M Finlay The Evolution of Landscape The Ocean and its Work (Swiney Lectures) (12)
- KING'S COLLEGE, LONDON, at 5 30—Dr A M. Blackman Egyptian Myth and Ritual

## TUESDAY, FEBRUARY 2

- LONDON SCHOOL OF ECONOMICS, at 5—Dr A F Meyendorff Modern Theories of Law The Psychological Theory
- UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 15—Dr E W Fish The Pathology of Dentine and the Dental Pulp

## WEDNESDAY, FEBRUARY 3

- ROYAL INSTITUTE OF PUBLIC HEALTH, at 4—Dr D M Connan The Social Burden of the Rheumatic Diseases
- SCHOOL OF ORIENTAL STUDIES (jointly with Royal Anthropological Institute), at 5—C W Hobley The Development of Native Education in Kenya
- BEDFORD COLLEGE FOR WOMEN (in Physiological Department), at 5 15—Prof S J Cowell Modern Aspects of Nutrition (Succeeding Lectures on Feb 10, 17, and 24)
- BELFAST MUSEUM AND ART GALLERY, at 8—J J Ward Wonderland of the Spiders

## THURSDAY, FEBRUARY 4

- SCIENCE MUSEUM, SOUTH KENSINGTON, at 4 30—Sir Henry Lyons Historic Meteorological Instruments
- KING'S COLLEGE, LONDON (at 40 Torrington Square, W C1), at 6—S P Turn Economic Conditions in Russia To-day The Shortage of Qualified Labour and the Seven Year Plan

## FRIDAY, FEBRUARY 5

- UNIVERSITY COLLEGE, at 5 30—H N Gresley High Pressure Locomotives—Prof H A R Gibb The Climax of Arab Culture

## SATURDAY, FEBRUARY 6

- HORNIMAN MUSEUM (Forest Hill), at 3 30—Prof J R Ainsworth-Davis Shell-Fish in relation to Man

## Official Publications Received.

## Co-ordination of Scientific Digests.

FEW matters are more disturbing to the specialist in science and technology than the increasing number of scientific and technical periodicals which are published each year. The World List of Scientific Periodicals issued in 1927 contains nearly 25,000 entries and is already out of date. Reliable estimates in 1931 indicate that about three-quarters of a million scientific and technical papers are published every year in some 15,000 current periodicals, and there are as yet no signs that the limit of expansion has been reached. The task of keeping in touch with all that is published even in a limited field is becoming a physical impossibility to the most rigid specialist, and industrial and scientific research are alike more and more dependent upon the abstracting bureaux for directing their attention to the papers which it is essential that the investigator on particular problems should read.

This tendency in itself throws a heavier responsibility on the various abstracting bureaux, for more depends upon their efficiency and vigilance. At the same time, the multiplicity of publications has greatly increased the strain on the meagre resources of the societies maintaining such services, and in recent months the British Bureau of Chemical Abstracts has been compelled by financial stringency to introduce abbreviations into its abstracts. Opinion is strongly held in some quarters that the innovation has introduced ambiguity and diminished the utility of the abstracts, but it is doubtful whether in the present circumstances the Bureau could as the alternative have raised the price of its Abstract publications.

The seriousness of the situation is fully realised by the officers of the Bureau, and a full discussion was held in May 1930 by the Chemical Engineering Group of the Society of Chemical Industry, at which Sir Frederic Nathan presented his paper on the international abstracting of scientific literature, outlining a scheme based on each country abstracting its own literature and the use of the International Decimal Classification for classification. The scheme was considered again at the conference of the International Institute of Bibliography at The Hague last August, and again by the Association of Special Libraries and Information Bureaux at its annual conference at Oxford in September. Mr H T Tizard, president of the latter Association, had already convened a representative conference at the Imperial College of Science and Technology in July for the informal discussion and interchange of experience on problems of preparing

and utilising abstracts of scientific and technical literature

The subject is one that bustles with difficulties, and co-operation even between the British and the American abstracting services is by no means simple to organise. It is clear, however, that the magnitude of the existing and rapidly increasing mass of scientific literature requires more systematic methods for its abstracting and classification than have been applied in the past. It may be that definite steps must be taken towards a comprehensive world scheme, even if it is only in one or two limited fields such as chemistry that definite proposals are possible in the near future. On the other hand, it is possible that, so far from the various technical abstracting services which at present overlap with scientific organisations like *Science Abstracts* and the British Bureau of Chemical Abstracts becoming merged in the latter, the scientific bureaux themselves may be divided and the abstracting of applied science be arranged by industries and not by sciences. It is not unlikely that more generous financial support might be received from industries for such schemes apart from the possibilities of co-operation with the efficient technical abstracting services which are already maintained by some industrial firms with large research departments. It is significant that the bulletins issued by the National Committees of the World Power Conference represent the first successful attempts at international bibliography.

Progress in any direction without overlapping and waste of effort is by no means easy, and in the meantime the danger of research work being duplicated in different parts of the world for lack of prompt and adequate means of exchange of information continues. With the idea of minimising the waste of scientific and technical effort in this way, apart from facilitating the exchange of scientific thought, a committee of scientific advisers, set up by the International Committee on Intellectual Co-operation, has considered the co-ordination of scientific bibliographies. With the object of assisting in the compilation of authoritative and complete bibliographies, the committee has adopted a recommendation that no scientific papers should be published which do not contain at the beginning or end analytical summaries compiled by the authors to facilitate the reading of the work or memorandum in question. The committee expressed the further opinion that the use of summaries should be extended to the reports of academic bodies, excepting very short articles or publications which are themselves in the nature of summaries.

The committee rightly insists that such summaries should conform to precise rules, failing which they lose most of their usefulness, and the rules recommended cover an exhaustive index of the subject, indicating new methods and results even though unconnected with the general subject of the paper as well as the conclusions and numerical data of general importance. A length four to eight per cent of that of the article is suggested.

This recommendation has been communicated to the Royal Society by the International Committee, with a request that it should be brought to the notice of all scientific organisations and editorial bodies responsible for the publication of scientific papers and communications in Great Britain. The council of the Royal Society, while generally favourable to the recommendation and its purpose, did not commit itself to the recommendation of the adoption of the proposed rules in their exact detail, but expressed the opinion that the recommendation could most usefully be brought to the notice of those concerned in the columns of NATURE.

It is obvious that original papers of the type to which the recommendation mainly relates are rarely published in NATURE. Nor are the summaries or reviews of research work included in our pages usually of sufficient length to justify even the enumeration of subjects proposed by the recommendation. There can, however, be little doubt as to the usefulness of providing an adequate summary with all scientific papers. Its value has already been demonstrated by the practice of providing an abstract of German, French, or English with the papers published in the Czechoslovakian, Rumanian, and similar scientific journals since the War. These summaries have greatly assisted in making more widely known the valuable research work being carried out in these countries in spite of the language difficulty.

The major criticism of the proposal will undoubtedly centre on the ability of the author to provide an adequate analytical summary even when furnished with rigid rules for its preparation. At the conference convened by Mr Tizard there was an interesting discussion as to the merits of authors as abstractors of their own papers, one delegate holding that the author, although the worst critic, was the best abstractor of his own work. Much would, however, undoubtedly depend on the editorial board to which the paper with its summary was submitted, for, apart from wide variations in the capacity of individual scientific workers to summarise or abstract their own papers, there is

the ever-present danger that the specialist mind which can best indicate the immediate and specialised bearing of the paper may completely overlook the general bearing of the paper which it should equally be the purpose of the summary to indicate. Co-operation between the author and editor might do much to remedy any such defect.

With papers published in the lesser known languages, such as Russian, a further difficulty arises regarding the language in which the abstract should be published. The whole purpose of the recommendation would be defeated if the summary were not issued in a generally known language, and probably it should be limited to English, French, or German. This raises a further obstacle to the preparation of an author's summary. While the knowledge of a foreign language is often deplorably small among scientific workers, it is even rarer to find a scientific worker who can write clearly and concisely in a language other than his own. Much greater linguistic powers must be assumed on the part of authors of scientific and technical articles if the preparation of such summaries is to be left to their own unaided efforts, and present experience of the abstracts provided in foreign languages does not encourage the assumption.

The same difficulty is, of course, encountered in regard to Sir Frederic Nathan's scheme for international abstracting, but while the difficulty is acute it should not necessarily be insurmountable. The very wide variation in the merits of the technical and scientific papers which are published in different countries, and even in the same country, tends, however, to discourage the expectation of early success. If steps could be taken simultaneously to secure some general improvement in the standard required for the publication of a paper in a reputable scientific journal, some general discouragement of premature publication, the repression of a widespread practice, for which some countries are notorious, of publishing the same investigation two or three times over in different journals without acknowledgment, and the curtailment of the practice of reprinting papers in different journals in the same country, real progress should undoubtedly be achieved. The selection of material and the discarding of the useless or irrelevant which are so essential in special libraries or information bureaux must be adopted judiciously but widely as fundamental principles both in publication and in abstracting.

Meanwhile the urgency of the problem continues unabated, with its tale of wasted effort, time, and money in every branch of science and invention due

to lack of information as to previous work. Vast stores of information are still out of reach which, when brought into juxtaposition with related facts in the mind of the investigator, might stimulate the growth of further knowledge and the birth of new ideas. The recommendations of the International Committee at least deserve the serious attention and careful study of all who realise the gigantic problem which scientific and technical literature now presents, and how long overdue is a determined effort for reform.

### The Sphere of Chemical Embryology.

*Chemical Embryology* By Dr Joseph Needham  
In 3 volumes Vol 1 Pp xxii + 613 + 11 plates  
Vol 2 Pp xvi + 615-1253 + 3 plates Vol 3  
Pp xvi + 1255-2021 + 1 plate (Cambridge At  
the University Press, 1931) 105s net

THIS is in its way a classical book. It is true, as T. H. Huxley said, that "books are the money of literature, but the counters of science", so that the term classical has a somewhat different connotation in the two fields. It is rare for a scientific book to conserve its scientific as opposed to its historical value through the centuries or even through the decades. There are a few which have done so. The "Origin of Species", for example, is one, and Wallace's "Malay Archipelago" is another, to go back, no one can read Harvey's "De motu cordis" without gaining new insight into scientific method and, indeed, into the physiology of the circulation, while one may prophesy that in its very different way D'Arcy Thompson's "Growth and Form" will long continue to make its own appeal.

Most of the classics of science are, however, classical because they mark a stage, like Linnæus's "Systema Naturæ", open a door, like Mendel's papers, consolidate a position, like Wilson's "The Cell". Dr Needham's book falls into this last sub-category. It demonstrates the extent of ground won by the pioneers in this new field, defines its scope, consolidates one part with another, and proclaims to the world the title of this young branch of biology from now on to sovereign rights in a territory of its own.

Faced with the formidable bulk of its more than two thousand pages, the reviewer cannot begin better than by giving an outline of its contents. The work opens with a short theoretical part, in which various biological philosophies are discussed with reference to the possibility of chemical embryology existing in its own right, and, this granted,

to the best method of prosecuting its study. The views of Driesch, Rignano, Haldane, Lloyd Morgan, E. S. Russell are discussed, as well as the early vitalistic controversies and the long battle over preformation and epigenesis, and the section concludes with an exposé of that well-thought-out 'neo-mechanism' with which those who have read the author's "Sceptical Biologist" are already familiar.

Part II, comprising nearly two hundred pages, is an extremely able and detailed account of the origins of chemical embryology, which, it may be prophesied, will long remain the best history of the subject.

Part III constitutes the bulk of the work, the treatise proper. To it we will return, after noting the existence of Part IV, with a number of special appendices, and Part V, with a two-hundred-and-fifty-page bibliography (and this with citation only of the author and the journal, not the title of the paper), an ample index of subjects, and another of the animals referred to.

Part III is entitled "General Chemical Embryology", and includes twenty-four sections: The unfertilised egg as a physico-chemical system. Growth. Differentiation. Embryonic respiration. The biophysics of development. The general metabolism of the embryo—its energetics—its special metabolisms—of carbohydrates, of proteins, of other nitrogen compounds, of fats, of lipoids and other oddments, of inorganic substances. Then the rôle of enzymes, hormones, vitamins, and pigments in development. The resistance and susceptibility of the embryo—its serology and immunology. The biochemistry of the placenta, of the amniotic and allantoic fluid. The blood and tissue chemistry of the embryo, and finally hatching and birth, on which follow fifty admirable pages of epilegomena, summarising some of the more salient ideas which emerged from the fourteen hundred pages of Part III.

This will at least give some idea of the ample scope of these three volumes, and demonstrate that it is impossible for a reviewer to offer any adequate criticism of details in his 'thousand words'. It will be best to give some idea of the interesting contacts which Needham's discussion offers with other fields of inquiry, for, since the scientific analysis of ontogeny is perhaps less advanced than that of any equally universal and equally important characteristic of living things, we must expect that a thorough exploration of any single one of its aspects will reveal many new contacts and unsuspected points of view.

Let not even the morphologists imagine that the studies are immune. The theory of recapitulation for example (p. 1629), suffers somewhat of a sea-change at the hands of the chemical embryologists. Consideration of the 'cleidoic' or closed system for example, of birds and reptiles, leads to a number of interesting and important evolutionary suggestions, and the discussion of its 'uricotelic' metabolism, in which uric acid instead of urea (or ammonia) is the final product of nitrogen excretion, suggests the important reflection that the type of metabolism characteristic of a group may often have been determined by the metabolic exigencies of embryonic life—a view which links up with those more morphological ones of Garstang on the importance of larval characters as stepping-stones to new evolution.

The *Entwicklungsmechaniker* will find much to interest him, including a valuable theoretical discussion of the problem of differentiation, and perhaps the best balanced critique of Child's theory of axial gradients which has yet appeared. Needham concludes one of his sections with the remark that the prerequisite for real and rapid progress in the scientific analysis of ontogeny is the linking up of the results of chemical embryology and those of *Entwicklungsmechanik*. With this we can all agree, but may add that Needham himself has thrown out a number of suggestions which will be of value in bringing about the liaison.

The physiologist will find a great deal to interest him. In the past, physiology has had a distinctly confined scope. Just as its virtual restriction to a few terrestrial vertebrate types has made the vista opened up by comparative study of other organic types so very alluring, so its virtual restriction to adult function means that the conception, opened up by these volumes, of a physiological as well as a morphological ontogeny will provide an equally dazzling prospect of research. It is by stepping backwards into developmental problems that morphology and physiology are ceasing to be 'pure' and are becoming parts of a synthetic and truly general biology.

Among specific topics of physiological interest may be mentioned the successive predominance of carbohydrates, proteins, and fats in the metabolism of embryonic life, the different methods adopted by marine, fresh-water, and terrestrial embryos for obtaining mineral substances and water, the apparently universal peaked curve for intensity of metabolism during ontogeny, rising to a maximum and then declining, the difficult but fascinating problems concerning the energetics of embryonic life, and

the temporal succession of various physiologically important substances, such as enzymes, hormones, and antigens, during development

Those interested in growth will find in the section on increase in size and weight a valuable summary, critical and up-to-date, of the various theories on the subject of growth, while specialists in mammalian embryology are presented with a full account of the metabolism and functions of the placenta

The general biologist will all the time be adding interesting items to his store of facts and ideas. Among these subjects the following may be mentioned. The notion that the activity of free marine larvæ may be concerned less with disposal than with the necessity of bringing large volumes of water in contact with the tiny organism to satisfy its need for phosphorus. The fact that the dogfish embryo excretes its urea into its yolk, so retaining it for osmotic purposes. The possibility that the shortage of mineral salts in fresh water may have been one of the major factors limiting the colonisation of this element by marine groups. The fact that one and the same tissue grown *in vitro* shows marked metabolic differences according to the age of the embryo from which it is taken, but that these differences disappear with prolonged sub-culturing. The curious progressive decrease of the melting point of human fat with age. The existence of numerous extra-embryonic enzymes during the early development of the chick, and the fascinating puzzle of how their operations are controlled before the control can be taken over by the embryo. The concordance of chemical with general biological evidence as to the intensely critical nature of the processes associated with gastrulation. The presence of subsidiary 'hearts' in the bat's placenta. The fact that the existence of special hatching enzymes in teleosts causes a veritable race between hatching and death, in which a slight fault of timing may prove fatal. The 'anarchistic' growth of oxygen-starved chick embryos, and the dislocation of differentiation from growth by means of cold. The fact that the semi-lethal yellow gene of mice exerts three different effects at three widely separated points in time during development. The existence of two groups of processes in embryonic life, one (including growth and differentiation) the maximum intensity of which falls early, the other (including metabolic rate) with a maximum intensity falling late.

So we might continue, but enough has been said to show what a mine of interest and information is to be found in Needham's pages.

There are naturally some minor criticisms to be made. The problem of dedifferentiation, whether

in its own right or in relation to metamorphosis, receives very scant treatment. No attempt is made to link up the discussion of Child's axial gradients with the important concepts of morphogenetic 'fields' associated with the names of Gurvich, Weiss, Schotté, and Bertalanffy. The implications of recent work on mitogenetic rays for the regulation of cleavage rate are not mentioned. It is a pity that the interesting appendix on the metamorphosis of insects has not been supplemented by a comparison with that of amphibia. Needham's surprise at the failure of insects to develop a placenta is perhaps misplaced: its advantage would be small in organisms of such limited size.

If there is a general criticism to make, it is that the book is sometimes ponderous in treatment, notably in sections dealing with disputed points, where it often reads like a series of notes on individual papers. If brief critical summaries could have been provided at the end of each section, it would have been very helpful.

The work, however, remains a classic. It has vindicated the claims of chemical embryology to independent and fruitful existence, and marks another mile-stone on the road biology is taking in its transformation from a static to a dynamic science. Biologists are under a very real debt to Dr. Needham for his wide reading, his critical and constructive faculty, and his patient industry, which have issued in this fine work. J. S. H.

### Archæology of the Amazon Basin.

- (1) *L'Archéologie du bassin de l'Amazone*. Par Prof. Erland Nordenskiöld. (*Ars Americana*, 1.) Pp viii + 72 + 57 planches. (Paris: Les Éditions G. Van Oest, 1930.) 350 francs.
- (2) *L'ancienne civilisation des Barréales du nord-ouest Argentin (La Ciénega et la Aguada) d'après les collections privées et les documents de Benjamin Muniz Baretto*. Par Prof. Salvador Debenedetti. (*Ars Americana*, 2.) Pp 60 + 68 planches. (Paris: Les Éditions G. Van Oest, 1931.) 350 francs.

(1) **T**HIS large quarto volume, illustrated by fifty-seven plates, many in colours, is the first of a series devoted to the art of aboriginal America. The series is published under the auspices of an international committee which includes representatives, all well known in the archæological world, from France, Germany, Sweden, Brazil, and the Argentine Republic.

The theme of this, the inaugural volume, is the archæology of the Amazon basin, and the author is the distinguished Swedish anthropologist and

traveller, Baron Erland Nordenskiöld, director of the Goteburg Museum, who in 1929 was awarded the Huxley Memorial Medal of the Royal Anthropological Institute of Great Britain and Ireland

A work dealing comprehensively with the archaeology of this area is as welcome to students as it is difficult to prepare. The territory is vast, and huge tracts of it, owing to the dense forests, never harboured a sedentary population. The same conditions which hampered the development of arts and crafts have also hampered exploration, and the archaeology of this great region is very imperfectly known.

Baron Nordenskiöld has given us an admirable survey of the archaeology of the country covered by the Amazon and its tributaries east of the Andes, based on a study of early travellers and his own personal expeditions, illustrated by such specimens as have been rescued from the earth by the very few excavators who have faced the difficulties provided by climate and forest. Added to the investigations of previous explorers are the results obtained by Mr. Curt Nimuendaju, whose recent expeditions on behalf of the Goteborg Museum, combined with the collections secured by Baron Nordenskiöld himself, have provided that institution with what is probably the finest series of Brazilian antiquities in the world.

In sixty-three pages of text and fifty-seven plates the author has succeeded in providing not only material and guidance for future workers, but also a number of soundly substantiated theories. He shows fairly clearly that, of the three important tribes inhabiting the Amazon east of the Andes (the Arawak, Carib, and Guarani), the Arawak provided the predominant influence in art, an influence extending northward to the Antilles, and even, faintly, to Florida, and southward into Bolivia. The incised pottery of Marajo and the modelled ware of Santarem, in spite of the difference of technique, display the same artistic traditions, and these are echoed in the primitive ware of the districts populated, in historical times, by Caribs.

Little trace of the great Andean culture, the pre-Inca and Inca, can be discerned except in the extreme south of the region under review. What traces exist relate only to the north-western provinces of Argentina, where there seems to be some mingling of influences emanating both from the early Tiahuanaco Empire and the Arawak culture.

It is not too much to say that the text is a model of construction and commentary. It is short, and the conclusions which the author offers are drawn directly from the evidence at his disposal.

As regards the illustrations, which constitute so large a proportion of the work, whether coloured or monochrome, it need only be said that both publisher and printer deserve the most sincere congratulations on the part of all students of science and art.

(2) The second monograph of the series carries a melancholy significance, because the author, Salvador Debenedetti, perhaps the leading archaeologist of Argentina, died unexpectedly on his voyage home from Europe, where he had been attending the International Congress of Americanists in Hamburg as Argentine delegate, and had conveyed the invitation of his Government to the Congress to meet in La Plata in 1932. He therefore never saw the publication of a volume to which he had devoted much time and thought, and which fully supports his reputation.

Debenedetti's introduction, though short, provides an excellent picture of what is known of the archaeology of the north-west Argentine Republic, and the sixty-eight plates, admirably printed, are a storehouse of design for students of primitive American art. The volume is a very good companion to Baron Nordenskiöld's monograph, because it shows the twofold influences of Amazonian art and the art of the early Tiahuanaco period of the Bolivian highlands, the latter predominating. Further, it provides very clear indications of artistic affinity with the art of the Nasca valley in southern Peru, in which Amazonian influences are almost indistinguishable. The art of Nasca and the north-west Argentine are definitely akin, but the technique is different. The majority of the Nasca designs are painted in coloured slip, the majority of the Argentine designs are engraved, or incised.

A comparison of the artistic motives illustrated in the two volumes, combined with what is known of the art of southern Peru, suggests that the early centre was Tiahuanaco, the influence of which spread to the Amazon, northern Argentina, and southern Peru, with a reflex action on the part of the Amazonian tribes which affected Tiahuanaco and Argentina more than the Peruvian coast.

The illustrations are taken from the magnificent collections made by the Benjamin Muñiz Barreto expeditions between 1925 and 1929 in the province of Catamarca. The excavations undertaken by Sr. Muñiz Barreto have produced the largest and most notable series of ceramic and stone remains illustrating the archaeology of the region, and the publication of this, proportionally small, selection of his private collection will be welcomed by all students of American archaeology.

### High-Frequency Alternating Currents.

*High Frequency Alternating Currents* By Knox McIlwain and J G Brainerd Pp xiii + 510 (New York John Wiley and Sons, Inc., London Chapman and Hall, Ltd., 1931) 30s net

THIS is a remarkably good book "No claim is made for originality of most of the material, for the presentation of new results, or for an exhaustive treatment of the subject matter." This disclaimer in the preface is in exact accord with our estimate in reading through the text. Moreover, it is not improbable that a reader depending on this book for all his knowledge of the subject would fail to recognise a wireless set when it was put before him. Yet the very essence of quantitative high-frequency work is set down here in a well-ordered array, with just that orientation and emphasis which many of us have had, painfully and with labour, to develop in default of such guidance as the authors now offer to our happy juniors. There is a measured neglect of much of the secondary matter that has cumbered and disbalanced preceding textbooks, there is no running away from detailed expansion in cases where a superficial treatment has in many previous texts left the student with a stock of unjustified certainties to unlearn.

It is to be observed that the authors define 'high frequency' in a way which is, in fact, illogical and unusual, but corresponds to the requirements of the radio engineer, who is concerned not merely with the radio frequencies—20 kilocycles per second or above—which are the mail-vans of his communication system, but with the audible frequencies which are the postal packets containing the intelligence to be conveyed. Accordingly, "the term *high frequency* will be used to designate any frequency used in telephony and sound reproduction, in carrier telegraphy and telephony, and in radio telegraphy and telephony. [It] may then be applied to frequencies from twelve cycles to 300 million cycles per second."

The first three chapters, dealing with the general phenomena of high-frequency currents, of resonance, and of coupled circuits, are followed by the longest individual chapter in the book, sixty pages on "Thermionic Vacuum Tubes." This chapter contains an adequate analysis of the unloaded and loaded triode, starting from a discussion of the diode, and proceeding to the development of the equivalent circuit of the tube, touching perhaps more briefly than might have been desired—even in these days of screen-grid tubes—on the import-

ant subject of the 'input impedance' of the loaded triode. A more complete mathematical analysis of the action of tetrode and triode, allowing for grid currents and variation of amplification factors, occupies a further thirteen pages of appendix.

To the chapter on amplification, which is on sound normal lines, succeed two of the most valuable chapters in the book, those on modulation (18 pp) and detection (23 pp). The phenomena of cross-modulation and allied effects, which are rapidly assuming primary importance in reception problems, are not treated. The exhaustive treatment of the simpler demodulation problems, with full tabulations of the audio-frequency terms resulting from 'plate current detection' and 'grid current detection', will, however, prepare the student for more specialised work on the response of the detector to two or more modulated signal voltages simultaneously applied.

Other important chapters, equally characteristic of the outlook of the book, are those on electric wave filters (45 pp) and transmission lines (28 pp). This is almost the first appearance in a general textbook of a 'student's guide' to two comparatively recent importations from 'line practice' into radio practice. No entrant into radio engineering can afford to be ignorant of the enormous scope and flexibility of filter circuits, nor is it merely in the increasingly frequent interconnexion of radio and line links that transmission line theory is essential. The antenna array on which depends the economy and efficiency of a purely radio channel must be designed by the transmission line engineer. In both these fields the authors' treatment lays a solid foundation for further reading.

The chapter on electromagnetic waves develops the Maxwell equations and applies them to radiation from antenna systems. It is followed by a chapter on reflection and refraction, in which the treatment of attenuation of radio waves in transmission is less satisfactory than is most of the material in the book. The last chapter is devoted to a useful discussion on electro-mechanical systems, with special reference, of course, to the telephone receiver.

The defect mentioned in the preceding paragraph is of the less important class of sins of omission, the sins of commission, in the form of definitely misleading or erroneous statements, are gratifyingly few. In one respect, however, the book in general will offend the sensibilities of the non-American reader. The reader familiar with the *Bell System Technical Journal* will not require a bibliography to show how much the authors owe to that remarkably

fine and generous periodical, and will join the authors and the reviewer in offering full measure of gratitude and admiration to its enlightened publishers. But he will not willingly accept the implication, in text and bibliography of the work under review, that the eastern hemisphere ceased to contribute to the science of high frequency alternating currents in the early years of the twentieth century. Clerk Maxwell, Drude, J. J. Thomson, and Richardson do find their way into the references, but it would be chastening to feel that the most readily checked framework in the book is really "in drawing". Each chapter of the book carries at its end a very useful bibliography. These fifteen tabular bibliographies contain 121 references (some naturally duplicative, but here treated as independent). The references to American periodicals number 81, to English 1, to Continental nil. Of 39 book references, 30 are American, 6 English, 2 are to the English translation of Drude, the remaining 1 to Pedersen's remarkable work published in English *ab initio*. The gold has been re-interred, must the laurels be transplanted too?

#### Medical Statistics.

*An Introduction to Medical Statistics* By Hilda M. Woods and William T. Russell. Pp. x+125 (London: P. S. King and Son, Ltd., 1931) 7s 6d.

QUITE apart from the academic consideration that vital and medical statistics now form an obligatory part of the education of students seeking the University of London's diploma in public health, the demand for information about the methods of vital and medical statistics is increasing. The most casual reader of the newspapers is now aware that population problems are of serious practical importance and that the publications of the General Register Office cannot be ignored. It is scarcely an exaggeration to say that the recently issued preliminary report on the census of 1931 is one of the most sensational documents which has appeared for years, and that he who reads it intelligently will understand what is meant by saying that civilisation is in the melting pot.

In order to read vital-statistical documents intelligently, some technical training is required. Published manuals tend to fall between two stools; either they bewilder the ordinary reader with mathematical formulæ or they are couched in dogmatic terms which irritate him. Miss Woods

and Mr. Russell have avoided both these dangers. They make no claim to provide a complete treatise on statistical methodology, and, at the outset, warn the reader that he must consult larger books if he wishes to become a fully equipped statistician. But, within the compass of 125 pages and without dogmatism, they have given information quite adequate to enable the reader to peruse with understanding *any* official report on vital or medical statistics.

The first two chapters deal with the nature of the original material and its tabulation. These are followed by a short but sensible chapter on charts and diagrams. The next two chapters discuss estimates of population and the measurement of birth and death rates. The following four chapters are of a more general character, but the illustrations are drawn from vital-statistical data. The next chapter is a clear account of the principles involved in the construction of a life table, and the last expounds the root idea involved in the determination of a 'probable error'.

Here and there the printer has failed to cope with a subscript notation, but on the whole the format is good and the reader should have no difficulty in following the exposition. This book deserves a wide circulation. M. GREENWOOD

#### Short Reviews.

- (1) *Race as a Political Factor*. By Prof. J. W. Gregory. (Conway Memorial Lecture delivered at Conway Hall, Red Lion Square, W.C.1, on April 15, 1931.) Pp. 72. (London: Watts and Co., 1931.) 2s net.
- (2) *Race Mixture. Studies in Intermarriage and Miscegenation*. By E. B. Reuter. (Whittlesey House Publication.) Pp. vii+224. (New York: McGraw-Hill Book Co., Inc., London: McGraw-Hill Publishing Co., Ltd., 1931.) 12s 6d net.

EACH of these two books deals, though from very different points of view, with the question of the effects of contact between two or more races differing in physical character and in culture—a problem which to-day is probably of more importance for the future of the world than any other with which public policy is concerned in the countries affected.

(1) Prof. Gregory's Conway lecture has the practical end very directly in view. His remedy for the present situation and the avoidance of a greater danger in the future is segregation of the inferior race. His argument is that otherwise social absorption is inevitable in present conditions, and the product of crossing races so diverse as black, white, and brown, so far as we are able to judge from the biological evidence, is likely to be of an inferior type. Further, in communities in which white and coloured live side by side, the

coloured so reduce the wages of the white low-grade labour as to render even their minimum standard of living unattainable

(2) Prof Gregory's argument rests largely on the inferiority of the hybrid. To this Prof Reuter's book is a foil. He points out that the weakness of all argument about 'superior' and 'inferior' races is that, mistakenly, it makes culture a function of race. He then examines in considerable detail, in a number of essays, various aspects of the colour problem in the United States but with special reference to the position and achievement of the mulatto and the lesser degrees of negro blood. He shows that, so far from being inferior, these crosses have attained a very high degree of achievement. He makes one very interesting point which is apt to be overlooked. In the case of the parents of a very large proportion of these mixed breeds, so far as the individual is concerned, the black has been exceptional in physical character and intelligence, while the white has often been of a low type intellectually or morally.

*Die westfälische Sedimentation und die asturische Phase in der innersudetischen Mulde.* Von S. von Bubnoff. (*Fortschritte der Geologie und Paläontologie*, herausgegeben von Prof. Dr. W. Soergel, Band 9, Heft 29.) Pp. iv + 407-497. (Berlin: Gebrüder Borntraeger, 1931.)

PROF. BUBNOFF has made a valuable stratigraphical and tectonic study of the Westphalian sediments of the Inner-Sudetic Basin in southern Silesia with the view of determining the relative duration of the Asturian phase of orogeny. The basin lies between the crystalline rocks of the Riesengebirge and the Eulengebirge, and is otherwise bounded by Lower Palaeozoic phyllites or by Kulm. A geological map which accompanies the book shows the limits within this frame of the successive basins of sedimentation in Namurian, Westphalian, and Stephanian times.

It is pointed out that the exact determination of the time of an orogenic phase is only possible where the earlier and later sediments can be exactly dated. As a result of the detailed work in the region described, it is clear that the Asturian phase was not a single episode of concentrated movement, but the sum of a series of differential disturbances which occurred throughout Westphalian time. The maximum intensity of movement occurred not at the close of the Westphalian, as generally stated, but during the later part of Westphalian time. The direction of movement deviated considerably from the trends of earlier and later orogenic phases. The development of each successive basin of subsidence is found to be related to an orogenic event.

It will be realised from these results that the author has made a contribution to comparative tectonics of great importance. Similar conclusions are being reached elsewhere (for example, in the Pennines and adjacent coalfields, in Wales, and in various North American areas) from a careful scrutiny of the sedimentary and structural record, suggesting that adjustment to stresses is more nearly continuous than has hitherto been realised.

*The Electric Trolley Bus.* By R. A. Bishop. (The Specialists' Series.) Pp. xi + 193. (London: Sir Isaac Pitman and Sons, Ltd., 1931.) 12s. 6d. net.

THE Royal Commission on Transport has suggested that the tramways are "in a state of obsolescence". It suggested also that the petrol bus has advantages as compared with trolley buses. The author points out that there are many reasons which make the trolley bus the more desirable. For example, if the whole of the 14,000 tramcars in Great Britain were replaced by petrol buses, the coal industry would lose one of its most important customers. Assuming that an omnibus takes a gallon for every five miles travelled, there would be an additional consumption of about 87 million gallons per annum. From the point of view of national economies, therefore, it is necessary that the load on the generating stations be retained. This is done when the change is made to the trolley bus.

The modern electric trolley bus is not being installed merely to replace obsolete tramway systems, in some cases it is being put into service where petrol buses previously ran because it is more efficient and considerably cheaper to operate. It has to be remembered also that the city street passenger systems are largely owned by the public and should be operated on the most efficient lines for the benefit of the public. This book is to be commended. Good chapters are given on "The Changing Outlook" and "On the Future of City Transport".

*The Chemistry, Flavouring and Manufacture of Chocolate Confectionery and Cocoa.* By H. R. Jensen. Pp. xvi + 406. (London: J. and A. Churchill, 1931.) 27s.

ALTHOUGH "the captains and the kings depart", the world goes on eating chocolates, particularly in countries where alcohol is prohibited. Further, since science and the chemist have penetrated into the industry, there is an amazing store of accumulated technical knowledge in every branch of it. As to how far the best use of this is made by British industry is a question over which the author breaks a lance in his introduction, as a past chairman of the panel of the British Association of Research for Cocoa, Chocolate, Sugar Confectionery, and Jam Trades, he is well qualified for the task. It is disturbing to notice that he is so far critical of the condition of affairs in Great Britain as to state that the failure to make effective use of the laboratory is both limiting the scope of the younger men and definitely reacting on the class of men who enter the industry.

The book is essentially a reference manual. It deals in turn with cocoa, with chocolate manufacture, with ingredients such as fats, sugars, milk, agglutinants, flavours, colours, and analysis. It is clearly printed, contains ample tables and the usual necessary illustrations from plant manufacturers' catalogues. Such problems as bloom, both sugar and fat, which are the bugbear of the manufacture, and other difficulties arising out of improper storage of chocolate goods are discussed briefly.

### The Dehra Dun and Saharanpur Herbaria.

THE Saharanpur Botanic Garden, situated in the old North-Western Provinces, India, was at one time in the charge of the late Mr J E Duthie, who was responsible for placing the herbarium of that place in an exceptional position. This herbarium was transferred later to the Forest Research Institute, Dehra Dun. Mr Duthie left numerous manuscript notes on the herbarium, and with their aid, Mr R N Parker, forest botanist, has published an account of "The Herbarium of the Forest Research Institute" \*.

Mr Parker tells us "The Herbarium of the Forest Research Institute is composed of two very unequal portions, the larger being the herbarium of the Botanical Department of Northern India, usually known as the Saharanpur Herbarium, which was transferred to Dehra Dun in 1908 and amalgamated with the herbarium of the Forest School. Nothing is now known of the relative sizes of the two herbaria. The present collection was estimated to contain 222,000 sheets on 1st January 1929." This brings the existing position of the herbarium nearly up to date. But to many the chief interest of Mr Parker's account will be found in the concise history he gives of the Saharanpur Botanic Garden, and the long line of distinguished botanists who had more or less connexion with it. To those who are acquainted with the botanical and, it may be added, the forestry history of India, such names as Govan, Wallich, Royle, Falconer, Helfer, Griffith, Hooker, Jameson, and J L Stewart will take them back to the earlier work accomplished in the first half of last century. For this reason it is proposed to glance briefly at some of the more important passages in this history of botany and the Botanic Gardens at Saharanpur, with which the name of Duthie (an excellent portrait of whom is reproduced in the *Bulletin*) will be for all time associated.

The Botanic Gardens were established in 1816 on the site of an old native garden, which was much enlarged at various times. The first superintendent was Dr Govan, who collected plants mainly in what is now Sirmoor State in the Simla district. A part, if not the whole, of his collections were listed with others in Wallich's Catalogue. What became of the plants is unknown, but a collection of drawings was ultimately presented to Kew. Dr Royle succeeded Govan in 1823, and the results of his collections were published by him after retirement in "Illustrations of the Botany of the Himalayan Mountains", which appeared in parts during 1833-40. In this work, Royle describes the area he explored and refers to a herbarium of 3500 species. He took the bulk of this collection home with him, there being no facilities for housing it at Saharanpur. This herbarium after his death was actually sold, by auction in London, for 11s, and is believed to have gone to Russia! Royle, however, presented a set of his plants to the Linnean Society and many of his plants are now

at Kew, some having been sent to Hooker or Bentham and going to Kew with the herbaria of these botanists. That Dehra Dun to-day possesses some of Royle's plants is chiefly due to the fact that in 1876, Duthie found some bundles of the former's plants at Saharanpur, which were preserved.

Owing to his medical duties (as station surgeon Royle was unable to undertake any botanical tours for the first three and a half years of his tenure at Saharanpur, but from a letter he wrote, dated June 28, 1828, it appears that he explored part of the Siwaliks and the Dun plateau, went up to Mussoorie, where he established an experimental physic garden, and marched across to Simla and on to Kotgarh. In the following year he made a more extensive tour in this part of the Himalaya. Wallich was superintendent of the Calcutta Botanic Gardens, and in the previous year had made the first botanical visit to the great forests of the newly acquired Province of Tenasserim and made some considerable collections.

Dr Falconer succeeded Royle in 1831. His collections were augmented by his adopting Royle's method of sending natives to accompany caravans into the interior of the mountains. These collections, with the exception of a few bundles found by Duthie with those of Royle, were sent to the India House, London. They are referred to by Hooker in the preface to the "Catalogue of the Plants distributed at the Royal Gardens, Kew from the Herbaria of Griffith, Falconer and Helfer." Falconer was also a geologist and investigated the fossil Siwalik fauna. Both Helfer and Falconer followed in Wallich's footsteps and were sent to report upon, and collect in, the forests of the Tenasserim Province in 1838-39 and 1849 respectively, the unrestricted fellings in the teak of that region having begun seriously to alarm the Government and the Court of Directors.

Dr Jameson followed Falconer in 1842, retiring in 1876. He was not a botanist, but had the credit of establishing the tea industry in Northern India. During brief periods of leave, Dr J L Stewart (first conservator of forests in the Punjab, 1864, and author of "Punjab Plants") officiated for him in 1861, and Dr G King, afterwards superintendent of the Royal Botanic Gardens, Calcutta, in 1868.

Dr Duthie arrived in Saharanpur in December 1876 as superintendent of the Botanic Gardens, which post he held until April 1, 1887, when he became director of the Botanical Department of Northern India, he was then able to devote his whole time to botanical work until he retired in December 1902. The position of affairs on Duthie taking over his charge is thus described by himself: "On my arrival in Saharanpur I found the Museum (erected in 1859) filled with miscellaneous collections including animals, mostly birds, as well as many kinds of vegetable products such as fibres, drugs, etc., and in one of the glass cases sundry articles used in the manufacture of tea were exhibited. Other cases contained various rock specimens,

\* *Forest Bulletin*, No. 73. The Herbarium of the Forest Research Institute. By R. N. Parker. Pp. iii+10. (Calcutta: Government of India Central Publication Branch, 1931.) 5 annas, 6d.

including some of Falconer's original specimens of the Siwalik fossil remains of animals. The herbarium, such as it was, occupied a very subordinate position of the Museum, for, as the specimens were unarranged, unmounted, and for the most part unnamed, the collection could not in that condition be considered of any practical use to the public. The material consisted mainly of specimens collected by natives employed by Dr Jameson during his tours in connection with tea culture. There were also a few bundles of specimens collected by Royle and Falconer in various parts of North-West India and labelled in their own handwriting. These, however, were mere remnants and scraps of their original collections."

Reference to Mr Parker's article must be made for a study of the methods by which Duthie grappled with the position and built up the magnificent herbarium, ultimately to prove so firm a foundation upon which the Dehra Dun Forest Research Institute could build.

Reference has been made to the Dehra Forest School Herbarium. This was started by Mr Gamble, who became director of the School in 1890 and held the position for some ten years. To start this collection, Gamble presented a set of his own duplicates collected in Bengal and Madras. He collected assiduously during his stay at Dehra and received many contributions from forest officers and others. Duthie also contributed, and the in-

structors at the School, especially Upendra Nath Kanjilal and Birbal, collected many species of local trees and shrubs. Some private herbaria made by forest officers were also presented.

Mr Parker details some interesting facts in connexion with the earlier collectors and their direct or indirect influence on the present herbarium at Dehra Dun. The names include Roxburgh, Wallich, Strachey, Winterbottom, Griffith, Helfer, Hooker *fil.*, Thomson, Stocks, Dalzell (Bombay), Wight (South India), Thomson, Beddome (conservator of forests, Madras and Bombay), Falconer, and Jameson. Amongst later collectors are the names of Col Davidson, R.E. (Kumaon), Dr Aitcheson (Punjab and Afghanistan), Dr Goodenough (collection received from Kew), Sir D Brandis (greater part of herbarium received from Kew), Thwaites (Ceylon), Gamble, Lace (Punjab, Baluchistan, Burma), Sir H. Collett (Simla, North-West Frontier, and Upper Burma), C.B. Clarke, C.F. Elliott (conservator of forests, Punjab and North-West Frontier), A.V. Munro (conservator of forests, Hazara, Multan, Baluchistan), C.W. Hope (many ferns), W. Gollan (superintendent of the Botanic Gardens, Saharanpur, 1887-1904—many plants and mosses), W.A. Talbot (conservator of forests—Bombay plants), Cooke (College of Science, Poona), and Dr Lisboa (grasses). The Herbarium also contains series of plants obtained by foreign exchanges.

### Intelligence and Fertility \*

By Dr SHEPHERD DAWSON

INVESTIGATIONS have recently been carried out in Glasgow into the relationship between birth-rate and intelligence. Individual Binet tests were given to more than twelve hundred children of ages three to fourteen years, and the results of these tests have been correlated with the size of the family to which each child belonged. The population studied was slightly below average both socially and intellectually, among the fathers of the children there was a high proportion of labourers, and the average intelligence ratio of the children themselves was about ten per cent below the average of the general population.

Most previous investigations have been concerned with birth-rates only. In the present inquiry, information was collected also regarding fatalities and survivals, as regards the family to which a child belonged, there was a record of the number of children alive, the number of fatalities (ante-natal, natal, and post-natal), the ages of the children and the parents, and the number of years the latter had been married.

Correlations were calculated between the intelligence of the child and (a) the number of surviving children in the family to which he belonged, (b) the number born alive, (c) the number of births, and (d) the number of possible lives. The correlations were all negative and small, but significant,

that is, they showed a tendency for dull children to belong to larger families, they were slightly higher when only those families were considered in which the age of the mother was forty-five years or more, and the family presumably complete.

By dividing the children into three groups, 'bright', 'average', and 'dull', with intelligence ratios above 114, 114 to 85, and below 85 (100 being the normal), it has been shown that the birth-rate in the 'dull' group is about 50 per cent higher than in the 'bright', while in the 'average' group it is about 35 per cent higher. The fatalities (ante-natal, natal, and post-natal) are most numerous in the dulllest families and fewest in the brightest, yet, in spite of this, the proportions of survivors at the time of the examination remained about the same, there were about 50 per cent more 'dull' than 'bright', and about 40 per cent more 'average' than 'bright'. In the completed families the differences were greater.

The dulllest children obviously came from the largest families. If it be assumed, as is commonly done, that, on the whole, the intelligence of children is like that of their parents, then the dull parents have, on the whole, slightly more children than brighter parents.

The question how far these results are representative of what is happening in the population as a whole is clearly of importance. There is ground for thinking that in a group which contains a higher

\* Substance of a paper read before Section J (Psychology) of the British Association in London on Sept 24.

proportion of brighter intellects, the difference between the 'dull' and the 'bright' in respect of size of family may be greater, especially if sterility also be considered. An inquiry made some years ago in Glasgow into mortality-rates in 1789 poor families and 455 that were well-to-do, showed that when only families of more than one child were included, the average number of possible lives in the former was 5.6, while among the well-to-do it was 3.2. 'Well-to-do' and 'intelligent' are not synonymous terms, but there is a correlation between intelligence and social position, at any rate, up to the professional grade. Galton's inquiries into the family histories of 180 Englishmen who had distinguished themselves in science pointed in the same direction, the average size of the completed families of these men of distinction was almost exactly the same as that of the 'bright' Glasgow group.

These observations, then, show conclusively that the birth-rate is highest among the dullest members of the community, and that, in spite of their higher fatalities, they appear to be leaving a larger proportion of survivors, for at the time of the examination there was a higher average of surviving children in the dull and average groups than in the other. It is a problem for the future to determine what proportion of the children in each group will reach maturity and establish families of their own, for, unless there is a much higher fatality-rate among the present survivors of the duller groups, it is clear that the less intelligent elements of the population are increasing at a greater rate than the more intelligent.

The problem is one of national importance, for, although a slight difference, even a difference of one, between the families of the 'bright' and the 'dull' may seem a small matter, it is really serious, for the influence of a differential birth-rate is prob-

ably cumulative, since people of the same intellectual grade tend to intermarry, and there is the possibility that the fertility of each grade may remain the same from one generation to another.

The only source of consolation in the dismal picture is the consciousness of our profound ignorance of some of the important factors in the situation. We have still to find the proportion of children of each grade of intelligence who survive to establish families of their own, we have to find to what extent the dull and the bright intermarry, and whether the fertility of each group remains constant. It is well known that superior intellects sometimes spring from apparently mediocre stock, but we still require exact information regarding the extent to which they pass on their brilliance to their children, the common belief is that able parents have, on the whole, gifted children, that mental capacity is inherited like stature and other physical characters. Also there are different kinds of dullness to be distinguished, dullness that is the result of pathological conditions, accident and disease, and dullness that is the result of traits inherent in the stock, and we are very much in need of methods of distinguishing these and assessing their incidence.

There is, however, clear evidence that the duller elements of society have bigger families than the more gifted, and the little we know about the fatalities among them suggests that dullness is being bred rather than intellect. In view of the tendency of the State and private enterprise to do so much for the unfit, it is obvious that the question of the relationship between intellect and birth-rate is of more than academic importance and requires careful study, not only of the facts regarding birth-rate and survival, but also of the laws of mental inheritance, for, until these are known, speculation on methods of treatment is somewhat futile.

### Intellectual Co-operation.

AMONG the subjects considered by the Executive Committee of the International Committee on Intellectual Co-operation at its thirteenth session last July, was a report from the Committee of Scientific Advisers appointed in April. This Committee had discussed the general question of the manner in which international intellectual co-operation can assist the co-ordination or organisation of scientific work, and had surveyed the various scientific matters which had already come before the International Committee.

The latter included a scheme of Prof. Cramer for the organisation of the documentation of chemistry, which the Committee of Scientific Advisers considered is primarily a question for the International Union of Chemistry, and in the field of bibliography the Committee limited itself to recommendations that authors' analytical summaries should be provided with all papers in scientific journals—a subject discussed elsewhere in this issue (p. 181)—and that, in agreement with the scientific unions, national centres for scientific bibliography should be established where they do not already exist.

A proposal from the French National Committee regarding the unification of scientific terminology was regarded as within the competence of the scientific unions unless the latter should desire to utilise the relations already established between them and the International Committee. Similarly, the Committee of Scientific Advisers in its report endorsed the resolution of the Committee of Library Experts on the standardisation of printed publications. In view of the great advantages offered to the whole of the scientific world by the adoption of uniform rules for the classification of printed works and their utilisation, the immediate adoption of a standard format for periodicals and a bibliographical cover note was recommended.

The present financial position of the fund for the publication of Tables of Constants and Numerical Data was considered, and the great value of this publication was stressed. To assist in the solution of existing difficulties, an agreement between the International Committee on Tables of Constants and the Unions of Chemistry and Physics regarding the scientific and material

organisation of the publication is desirable, and it was recommended that, following agreement, the International Committee on Intellectual Co-operation should support the International Committee in action taken to secure regular contribution by all countries of the funds required for the publication.

In the discussion on this report, the value of international bibliography was stressed, although it was agreed that Prof Severi's scheme for the organisation of an international centre for mathematical bibliography is primarily a matter for the International Union of Mathematics. On the other hand, opinion was freely expressed that the Committee should extend its scope to include the bibliography of historical, economic, and social sciences. Against the latter proposal, M Poincaré and Prof J T Shotwell urged that the methods required for preparing bibliographies of the exact sciences are entirely different from those which should be adopted for historical, legal, and social sciences, requiring the co-operation of specialists in the various exact sciences. Accordingly, no advantage would accrue from such an extension of the Committee's scope. It was further suggested that the Institute should inquire of the national scientific unions what means they have of obtaining information on the scientific output of their countries, and thus providing a foundation for an international bibliography of each science.

In a slightly different field is the proposal by Prof Cabrera for a repertory of scientific laboratories. This proposal was unanimously approved by the Committee of Scientific Advisers, who requested the International Committee to have the present situation in the laboratories studied by the Institute from the point of view of the working facilities accorded to foreign professors and students and the practical means of making the existing facilities known. So far as Great Britain is concerned, this information is largely contained in the "Year-book of the Universities of the Empire", and it was suggested that application should be made to the national committees in all countries where such committees exist. The national com-

mittee would be able to state whether a suitable year-book is published in the country which, as such or in modified form, could serve as a repertory. Even members of the International Committee who had questioned the advisability of continuing the Committee of Scientific Advisers were strongly in favour of this proposal, which was embodied in a resolution, expressing the opinion that a repertory of scientific laboratories would be a valuable supplement to the publications of the Institute and that its preparation might immediately be considered by the Institute.

Apart from such questions bearing on the interdependence of research and instruction, the Plenary Committee discussed a number of other matters of great interest to scientific workers. The results of the consultation with governments regarding the draft convention for the protection of intellectual rights were reviewed together with the results of a meeting with representatives of legal institutions and, considering the scientific advisers' recommendation in favour of recognising the rights of the scientific worker, it was agreed to establish a committee of specialists to consider, with the assistance of the Institute, the whole of the replies received from governments, with any other documentary information collected, and to continue the action already initiated.

The publication of an international code of abbreviations of titles of periodicals has now been completed in regard to Slav terms, and a proposal for the preparation of an international bibliography of translations was approved, a preliminary technical study of the necessary methods by the Institute being recommended. The scientific study of international relations, university exchanges, the international use of the cinematograph in education, the utilisation of leisure in general education, popular arts, educational cinematography, etc., are other topics coming within the scope of the International Committee, which, with the assistance it is giving towards the reorganisation of education in China, illustrate its great potentialities for raising the general level of intellectual life.

### Obituary.

SIR ALFRED YARROW, BT, FRS

MY first long talk with Sir Alfred Yarrow was at Oxford in 1926, during the British Association meeting. Yarrow was at that time much interested in the relation between the world's output of gold and the cost of living index figure. A year later he read a paper on the subject at the British Association meeting at Leeds. I knew little of the matter, but I listened to him with interest. Later on, at Brighton, we discussed the future of scientific societies and technical institutions, and particularly the relative merits of short term donations and endowments for perpetuity. It was a most interesting talk, and we agreed that only in exceptional circumstances were perpetuity endowments wise, and that it was better for capital and interest on donations to be spent within twenty

years or so, and to leave subsequent generations to do their bit. Yarrow thereupon told me he proposed giving me £5000 for the British Association, the capital and interest on which were to be spent within twenty years. I asked him not to spoil a very pleasant evening by putting me in the position of a beggar, and suggested the donation could wait. He agreed, but shortly after midnight he wrote out a cheque, and handing it to me, said, "I have doubled it—there is £10,000."

This principle of giving money to be spent within twenty years appealed to Yarrow very much, and whenever he read an announcement of a gift stipulating similar conditions he sent me a line expressing his pleasure. From that time I dined with Yarrow some ten or twelve times every year, and my respect and affection for him grew steadily

stronger. One of the proudest moments of his life was when he was elected a fellow of the Royal Society, the proceedings of which he followed with great interest. He read a large amount of scientific and technical literature, familiarising himself with all the latest developments of modern engineering and many of the more important discoveries in biology and biochemistry. He questioned me for more than two hours in November last about Sir Frederick Gowland Hopkins' presidential address to the Royal Society, and the recent work on vitamins. Fortunately I was familiar with some of the recent literature, but it was evident that he had read much more.

Always Yarrow's mind was singularly clear, and not only could he describe in detail his early work on the Thames, on the Clyde, his experiences during the War, and the latest improvements in ship-building, but also he was continually inventing new devices. The road-rail car was developed in Yarrow's mind long before such a car was built, and he was convinced that it would be an important factor in the development of the railways. He also sketched out a project which, had he been a younger man, he would have developed. It was to facilitate rapid transport across Europe, and particularly across Canada. In the scheme he had in mind, transport was to be by aeroplane during the day and in train sleeping-cars by night. In his ninetieth year he travelled by aeroplane a great deal, and although slightly deaf, he listened whenever possible to the throb of the engines in order to detect any failure on the part of a sparking plug. He declared that he had never known one to fail. The development of the London-Brighton line greatly interested him—possibly because of his stay at Brighton for long periods—and he worked out from data given in the technical press the relative merits of traction systems using steam, the Diesel engine, and electricity, making various hypotheses on the increase in passenger traffic.

Yarrow's very early work in life has been insufficiently described, long before he built the water-tube boiler he studied the motion of hot water in glass tubes, varying the conditions of pressure and temperature and noting the size of bubbles and their effect on the circulation. I believe that no full description of this work was published, but he was so impressed with the readiness of application of the results that he never wavered in his faith in laboratory experiments. His work on the resistance of ships at high speeds in deep and in shallow water, on propellers, and on the balancing of engines, is well known, but little is known of the small-scale experiments subsequent to sea trials.

In simpler matters, too, Yarrow's mind was very active. I remember a long talk we had on the subject of medals awarded by scientific societies. He pointed out that they were invariably tucked away in a drawer or deposited at a bank, and were rarely seen by the recipient and practically never by friends. Yarrow was of the opinion that such medals should be a source of inspiration, and devised a simple kind of mount so that a medal could be

hung on a wall or supported on a mantel. Better still, the medal might be sunk into a nice block of clear glass and used as a paper-weight, so that it could be seen while the recipient was at work.

An illustration of a different kind is associated with the 'Compleat Angler' at Marlow, which he bought, so he said, to show that an engineer could run an inn. He supplied some of the waiters with pedometers, and was astonished to find that on one Sunday a waiter said he had walked twenty miles. With a twinkle in his eye he said "I took the pedometers away in case they should ask for an increase in wages." To help the waiters and also to lessen the irritation produced when guests desired attention, he caused to be placed on each dining-table a telescopic tube flying a small Union Jack with a notice at the base "When you want the waiter, raise the flag." I give this illustration to show that Yarrow was ingenious in the smaller matters of life as well as in the larger ones.

Yarrow was rarely deceived by anyone, but he told with great relish how his firm sold the *Caroline* during the Russian-Japanese war to two Irish gentlemen who paid an instalment in advance. Yarrow had previously constructed the high-speed yacht *Tarantula*, which was built on the lines of a torpedo boat, and its speed was thirty knots which was very high in those days. The *Caroline* was of similar design, but it was only completed to a certain stage so that it might be fitted up either as a torpedo boat or as a fast yacht. She left the Thames hurriedly, had an exciting passage through the Kiel Canal, and was delivered to a Russian admiral at Libau. I understand that representations were made by Japan, and *Punch* had a cartoon depicting Russia with Yarrow's *Caroline* under her arm, while Japan cried out, "I thought you weren't selling any." Yarrow admitted that both he and the *Caroline* were sold handsomely on this occasion, and as he humorously put it—"The *Caroline* got to Russia, but left many 'care lines' on me."

Yarrow's generous gifts to scientific bodies, the London Hospital, Girton College, and the Yarrow Home at Broadstairs, total more than £500,000. However, not all of his scientific friends can be fully aware of the very kind and generous heart he had. By accident I have come into contact with some who have benefited by his kindness, and I do not wonder at the very great affection with which he was held.

F. E. SMITH

#### MR. R. W. WILLIAMSON

WE regret to record the death of Robert Wood Williamson, anthropologist and former treasurer of the Royal Anthropological Institute, which took place on Jan. 12, at the age of seventy-five years. The son of Prof. William Crawford Williamson, F.R.S., he was born in Manchester in 1856. After being educated privately and at Owens College, Manchester, where he took a degree in engineering, he took up law. A successful career as a solicitor was brought to a close voluntarily in 1908, at the early age of fifty-two, in order that he might devote himself to scientific research.

Acting under advice, Williamson elected to visit New Guinea and the Solomon Islands as fields still offering scope for anthropological exploration. In 1910 he started out, and penetrated the interior of New Guinea, where he spent some time in the villages of the Mafulu, a mountain people until then practically unknown, recording their customs and magical beliefs. The scientific results of this expedition were published in "The Mafulu Mountain Peoples of British New Guinea", which appeared in 1912. The personal narrative of Williamson's experiences, including his travels in the Solomons, was published a short time after in "The Ways of the South Sea Savage".

For the remainder of his life, Williamson devoted himself to the study of the ethnology of Polynesia. He set himself to the stupendous task of preparing a complete critical digest of the literature relating to Polynesia, with special reference to the central area. This was a work for which Williamson's acute critical faculty and his legal training peculiarly fitted him. The first instalment appeared in 1924

under the title "The Social and Political Systems of Central Polynesia", a monumental work, very fully illustrated, which will be of permanent value as an authority on the formal aspect of Polynesian institutions. In the succeeding years he prepared a large amount of material for the work which was to follow. It may be hoped that this will be preserved for reference, if not for posthumous publication.

From 1912 until 1921, Williamson was treasurer of the Royal Anthropological Institute, afterwards becoming a councillor and vice-president. His judgment and his counsel, tempered by a lawyer's caution, but undismayed by difficulties, were highly valued by his colleagues.

In addition to his professional and anthropological activities, Williamson was devoted to gardening, and was at one time well known as an amateur grower of rock-plants and alpinists. The gardens on his estate became public property after he left Manchester for Witley, near Godalming, his summer residence in his later years.

### News and Views.

#### Tariffs and Imported Scientific Books.

ON Thursday, Feb. 4, after this week's issue of NATURE has gone to press, the House of Commons is to hear a statement from Mr. Chamberlain of the Government's proposals for the imposition of a ten per cent duty on all imported goods with certain exceptions, and for the setting up of a Tariff Commission. As imported goods include scientific books and periodicals, we hope that a member of the House, perhaps one of the universities' representatives, will have an opportunity of putting the case for their exclusion from the proposed ten per cent duty. The revenue that would be obtained from the duty on such books would be trifling, while the imposition of the duty would add to the cost of scientific literature. The high prices of Continental publications have been commented upon in our columns on several occasions, and any action which would increase them would result in a further reduction of the number of such works purchased by scientific societies or individuals. With works of fiction and other literature having large circulations, the probable result of a tariff would be the printing of the publications in Great Britain. Scientific and technical publications belong, however, to a different category, their circulation must always be so small that printing in Great Britain could never be contemplated as a business proposition. Their success always depends on international circulation. The only result of a tariff would be to prevent scientific investigators from consulting works dealing with their particular subjects, and thus to hamper progress.

#### Agricultural Industry

THE fall in the price of agricultural produce in all countries has resulted in a depression, so long continued and so intense, that it is certain to lead to far-reaching changes in agriculture itself. One of these is now becoming evident. Agriculture is rapidly

becoming an industry dependent on the market, and is ceasing to be a mode of living for the great mass of the people engaged in it. Both the farmer and the peasant sell most of what they produce and buy most of what they require. They are in business and the market dominates them. This fact must be kept steadily in view in considering the future development of the industry. Up to the present, the application of science to agriculture has been concentrated on the discovery of improvements which can be applied within the existing structure of the industry. This no longer suffices. What is now needed are fresh approaches to the problems of production and distribution. The framework of the industry itself must now be added to the list of subjects for investigation, so that new and novel means can be found to increase the output per unit of capital and per unit of labour. One such experiment, in which the small holdings of the peasant have been converted into large-scale communal farms, is now in progress in Russia. Proposals for experiments in new methods of farming have recently been before our own Parliament, but have had to be dropped for the present for reasons connected with the general financial position. Another obvious field of experiment lies in the educational domain, in extending the area from which the industry is recruited, so that new ideas and new points of view may rapidly gain adherents.

#### An Opportunity in India

AN interesting experiment in agricultural education and training is now being undertaken in India by Capt. J. W. Petavel, at Kamshet, near Poona. An area of five hundred acres of suitable land, close to the railway line between Poona and Bombay, in a good climate and provided with facilities for the development of irrigation, has been secured for trying out a novel method of preparing the sons of the Indian

intelligentsia for a career on the land. The project received the active support of the late Sir Ashutosh Mukherji, vice-chancellor of the University of Calcutta. The idea underlying the scheme is the creation of an educational and training colony in which practical work in agriculture can be combined with ordinary schooling. The boys will be prepared for the usual examinations, but will take part in the growing of crops and in the care of animals. This will be possible by reducing the time devoted to study by two hours daily, so as to make room for three hours' productive work in the fields. An effort is being made to collect the best boys possible and not to confine recruitment to any particular class. It is hoped, in this way, to attract to the land a number of youths who otherwise would merely increase the army of unemployed university graduates now such an acute problem in India. So far, all efforts in this direction which have been made in the past have failed. Great changes in the outlook of educated India are, however, now taking place. The dislike of manual work which, a quarter of a century ago, used to be such a marked characteristic of the higher castes is rapidly disappearing. There is at the moment nothing impossible in the idea of utilising large numbers of the new generation for the development of agriculture—India's greatest industry. All that is needed are successful experiments, followed in due course by effective publicity.

#### Prehistoric Cornish Village.

RECENT excavations in the prehistoric village of Chrysauster, ten miles from Penzance, under the Ancient Monuments Branch of the Board of Works, have added considerably to the evidence bearing on the age and character of one of the most interesting of 'British' settlements. The exploration of the large house opened up by Mr T. D. Kendrick in 1928 has been completed, two houses untouched by previous explorers have been completely excavated, and the round walls and floors uncovered by Borlase in 1873 and J. B. Cornish in 1897 have been cleared. This settlement, of which eight houses remain over-ground, with the remnant of its covered pathway of approach, entered by a granite arch, strongly recalls Skara Brae in the Orkneys, which has recently been excavated by Prof. Gordon Childe. The resemblance of the structures to those of Skara Brae is noted by the writer of an article on Chrysauster which appeared in the *Times* of Jan. 23, but the author would appear to be imperfectly acquainted with the character of the former site. He is in error in regarding Chrysauster as the only known example of prehistoric houses lining along either side of what is apparently a village street, for this arrangement is one of the most characteristic features of Skara Brae. The northern site is more primitive in character, and undoubtedly earlier than Chrysauster, of which the occupation is now dated by the pottery at from about the first century B.C. to the second century A.D. Some of the pottery suggests coarse imitation of contemporary Roman ware. The inhabitants were in part agriculturists, as is indicated by the lynchets

behind the village, and, in all probability, tin-streamers. Tin-slag and lumps of shapeless iron have been found, but little else indicative of the character of the material culture.

#### Regional Smoke Abatement.

AN observer looking from a height upon a town of considerable size, whether industrial or otherwise, cannot fail to be impressed by the foul condition of the atmosphere below him. A thoughtful person can scarcely fail to marvel at the indifference of the public to the nuisance and its inertia towards remedial measures. The law in Great Britain relating to smoke abatement has hitherto been administered by local authorities, and while in some cases it has been efficiently and successfully applied, in many others it is either a dead letter or applied only intermittently. Ample provisions exist, however, for the formation of statutory regional authorities by means of which uniform and more thorough administration over any suitable geographical unit may be instituted. So far, only one such authority, the Sheffield, Rotherham, and District Smoke Abatement Committee, has been set up. The Council of the National Smoke Abatement Society met at York on Jan. 26, and passed a resolution that local authorities be urged to combine for the purpose of setting up suitable statutory regional organisations for the administration of smoke abatement law, that, pending the formation of statutory regional organisations, local authorities be urged to establish advisory committees similar to those already in existence, and that the support of the National Smoke Abatement Society be given to such projects as will further these proposals. The Council's report shows that regional effort should be both more economical and effective than local action only, which is often rendered useless by the apathy of neighbouring areas.

#### Development of Lighthouses.

THE paper by D. Alan Stevenson on lighthouses which was read to the Royal Society of Arts on Dec. 2 and is published in the Society's *Journal* for Jan. 15 is of great interest. Mr. Stevenson comes from a family which for generations has been responsible for the lights and aids to navigation on the Scottish coasts. R. L. Stevenson was one of this family. Up to just over a hundred years ago a fire set on the top of a tower and exposed to all conditions of the weather still continued to be used in Britain. There are grounds for supposing that this method dates back to the twelfth century B.C. The author and his father have just been awarded a special prize by the Royal Society of Arts for their invention of the talking beacon, which combines radio and fog signal methods most satisfactorily. Many people estimate the distance of a flash of lightning by noting the time between seeing the flash and hearing the thunder. Dividing this time expressed in seconds by five gives a rough approximation to the distance of the flash in miles. Similarly, if we use fog signals and radio waves, the distance of the beacon from the ship is found in nautical miles by dividing by  $5\frac{1}{2}$ , the

radio waves travelling practically instantaneously and the air waves with the velocity of sound. In the Stevensons' method, the ship does not need a stop-watch, only a simple radio receiver and a loud speaker, and the mariner is told in speech his exact distance at any time from the beacon whenever he hears the sound of the fog signal through the air. Suppose, for example, that the third blast of the air fog signal is heard by the navigator when the loud speaker is saying 'one mile two cables', then this is the distance of the ship from the beacon. This system has been tried out successfully on the Little Cumbrae Island in the Firth of Clyde for the last twelve months (see NATURE, Jan 24, 1931, p 138).

#### Czechoslovakian Broadcasting Station.

ONE of the smallest countries in Europe, Czechoslovakia, now possesses the most powerful broadcasting station in the world. It is situated near Cesky-Brod, some twenty-two miles east of Prague, and is near the geographical centre of Europe. The power of the station is 200 kilowatts, which places it well ahead of the 158-kilowatt station at Warsaw, the next largest. The power is derived from a 15,000-volt three-phase high tension line by Hewittic rectifier valves in oil-filled tanks, duplicated so as to avoid the risk of a breakdown. It was opened on Nov 21, but the power is temporarily restricted. There are two antennae towers, each 492 feet high and spaced 820 feet apart. The building has a copper roof, which is connected to the ground by a copper conductor. As there is also a copper mesh screen on the floor of the radio room, all the radio apparatus is actually contained within a copper screen. Switching arrangements enable the station to be worked either at half or full power. In the former case six valves are used in the final stage, and in the latter twelve valves. An ingenious counting device indicates the number of times a valve has operated the circuit breaker, and hence the behaviour of each valve throughout its life is recorded. The engineer supervising the working of the transmitter sits at a 'monitoring desk'. He listens at various stages to the speech or music passing through the transmitter and so can compare the quality at each point. Push buttons enable him to start up the motor generator sets and the pumps for the water-cooled valves. The wave-length is 486.2 metres, and it will be interesting to listen to this station when it is operating at full power.

#### Constants of High Voltage Lines

IN a paper by J. S. Forrest published in the December number of the *Journal of the Institution of Electrical Engineers*, instructive data are given about the 'constants' of the high voltage lines used in the national 'grid' of Great Britain. Twenty years ago, engineers considered merely the coefficients of electromagnetic induction between neighbouring power lines. Experience, however, has proved that the electrostatic coefficients are in many cases much more important. If we have two parallel lines, one maintained at a high voltage and the other insulated, a voltage will be induced in the latter which can be computed when the mutual electrostatic coefficient between the two

is known. Many years ago, Kelvin and Maxwell showed how these coefficients could be calculated, and now engineers are beginning to adopt their methods. The experiments described in this paper show that when the pressures on the live wires are 132 kilovolts, the induced pressures on neighbouring 'dead' wires may sometimes be thousands of volts. Experiments were made by measuring the resistance of a fisherman's line when wet with river water, to find out whether he ran any risk of getting a serious shock if his line hit a live wire. It was found that the resistance of the line measured half a megohm per centimetre length, and it is inferred that, provided the line beyond his rod be several yards in length, there is little risk. We do not agree with this conclusion. A few years ago an engineer, thinking that a 33,000-volt line was dead and wishing to measure its sag, threw up his measuring tape, which was not of metal, over it, and was instantly electrocuted. We feel certain that a fisherman would run a very serious risk if his line touched a high tension wire at a river crossing.

#### Physiology and the 'Aura'.

AT the annual general meeting of the British Psychological Society on Dec 19, Prof. D. F. Fraser-Harris read a preliminary communication on a physiological study of the human 'aura', as it is called by occultists. By the 'aura', or 'human atmosphere', spiritists refer to a misty emanation which envelops the living body but cannot penetrate the clothes. Unless the body is naked, the aura can be seen only around the head, hands, and fingers. A typical experiment claimed to demonstrate the aura is as follows. Hold the outstretched fingers of the two hands touching one another at the level of the eyes about a foot or so in front of a black background, then after staring at the finger-tips for about fifteen seconds, slowly draw the fingers apart, when the aura in the form of 'greyish mists' will be seen streaming from the ends of the receding fingers. At the outset, Prof. Fraser-Harris said that he questioned the accuracy of these observations. What are actually seen are very dark or black areas corresponding exactly in shape to the fingers, and *interdigital* spaces filled with the 'greyish mists'. His explanation is that the black areas are the negative after-images of the pale fingers viewed against the black background and produced by temporal retino-cerebral induction. The grey mists of the interdigital spaces are the whitish after-images of the corresponding spaces of the black ground similarly produced by this form of induction. That the phenomenon is optical and subjective is shown by the fact that when the conditions are reversed the after-images are also reversed. It is claimed, therefore, that the so-called 'aura' of fingers (or hand or head) has nothing to do with vitality, and, under the conditions just observed, is the familiar negative after-image produced by temporal retinal induction.

#### The Appeal of Natural Beauty.

IN the third Rickman Godlee Lecture, delivered in University College, London, in October, Prof. G. M. Trevelyan directed attention to the call and claims

of natural beauty The appeal of beauty he analysed into elements partly æsthetic and partly belonging to the primitive nature of man, whose emotions react to the combined reality and allegory of the recurrence of natural events But the reaction is not the same for all nations or for all times Two hundred years ago the southerner looked upon the mountains of Scotland as "monstrous excrescencies" upon the face of Nature, the bare rocky summits of which "produce the disagreeable appearance of a scabbed head", and the "stupendous bulk, frightful irregularity, and horrid gloom" of which can stand no comparison with the verdant beauties of Richmond Hill There has been a great change in æsthetic appreciation since that day, due perhaps to the removal of dangers which were thought to lurk in the gloom of deep mountain glens, perhaps to an outlook modified by the moral and intellectual changes of modern civilisation In any event, beauty has become the "highest common denominator in the spiritual life of to-day", and the change calls for action, and speedy action, on the part of the State, if natural beauty is not to be hopelessly lost in ill-planned developments which deface the countryside The lecture has been published by University College, price 1s

#### Museum Service for Schools

THE Board of Education has taken to heart the hints and recommendations made in the reports upon museums by Sir Henry Miers and by the Royal Commission on National Museum and Galleries, and has prepared a pamphlet on "Museums and Schools", which ought to be of service to both (H M Stationery Office, 9d net) A short historical summary traces the gradual converging of the interests of museums towards education and of the schools towards making use of the treasures stored in museums, but the most useful part is the chapter dealing with possible methods of co-operation between the two The loan of exhibits, the sale of reproductions, the use of temporary exhibitions, the visits of school children generally to be conducted by the school-teachers themselves, are described as desirable means of inter-communication, and great stress is laid upon the interest of the teacher himself It is a strange thing that while the Ministry of Agriculture and Fisheries can publish attractive pamphlets about rats, pigs, or poultry, this Board of Education pamphlet upon museums should appear in an unusual and therefore awkward size ( $7\frac{1}{4}$  in  $\times$  5 in), in rather small print arranged in 76 numbered paragraphs, and in dingy grey covers, the whole suggestive of that depressing museum feeling against which the pamphlet tilts its final paragraph

#### Andrew Balfour Memorial Fund.

AN appeal has been issued for funds to establish a memorial to the late Sir Andrew Balfour It will be recalled that Sir Andrew died in January last year, shortly after his appointment as the first director of the London School of Hygiene and Tropical Medicine, and an appreciation of his life and scientific work appeared in our columns in the issue of Feb 21 (p 279) Sir Andrew Balfour will

long be remembered for the work he did in the furtherance of research and study in tropical medicine and hygiene When funds are available, it is proposed to place a simple and inexpensive monument in the School, and with the remainder of the sum received to establish an 'Andrew Balfour Memorial Fund' for the purpose of aiding students, preferably those from overseas, to pursue courses of study at the School Contributions should be sent to the Honorary Treasurer, Andrew Balfour Memorial Fund, London School of Hygiene and Tropical Medicine, Keppel Street, London, W C 1

#### Bats as Carriers of Rabies

A RECENT report to the Legislative Council of Trinidad states that twenty persons died in South Trinidad between 1929 and 1931 of a disease considered by Dr Hurst, of the Lister Institute, as due to the virus of rabies of a hitherto unknown type The infection was not conveyed by dogs, as the last case of dog rabies was in 1914 The report suggests that bats may be concerned, and the *Trinidad Guardian* observes that since the issue of the report, Dr Paman, the Government bacteriologist, says that he has found typical rabies symptoms in the brain of a Sangre Grande daylight bat—whatever species that may be It is possible that a vampire, in attempting to suck the blood of a rabid dog, might be snapped at and escape with some injury sufficient for inoculation, when it would naturally bite and infect bats of its own and other species, the gregarious habits of bats, several different species of which often select the same retreat, being particularly favourable to the spread of such infection

#### Simpler British Coinage

THE address on simpler British coinage delivered by Mr Harry Allcock before the Manchester Society of Chartered Accountants appears in full in the December issue of the *Decimal Educator* He proposes to divide the shilling into 10 pence and to issue the following coins The pound of 200 pence, ten shillings of 100 pence, five shillings of 50 pence, two shillings of 20 pence, one shilling of 10 pence, half-shilling of 5 pence, two pence, one penny, half penny, and farthing, 10 coins in all He points out that while this system simplifies our coinage to the nations to whom we wish to sell our products, it also allows us to continue to divide the pound into halves, quarters, eighths, sixteenths, and thirty-seconds if necessary No new names are required, and  $1\frac{1}{2}$  new pence would be equal to  $1\frac{1}{2}$  old pence Mr Allcock contemplates the introduction of the new system by Government decree raising the value of the present penny and requiring each holder of pence to return one-sixth of them to H M Treasury, but he sees the difficulty of enforcing this in the case of private holders

#### Coroner's Law in the United States

*Bulletin* No 83 of the National Research Council of the National Academy of Sciences, Washington, D C, is entitled "A Compendium of the Statute Law of Coroners and Medical Examiners in the United States" It has been compiled by George H Wein-

mann and is issued under the auspices of the Committee on Medico-legal Problems of the Council (Washington, D C, 1931 3 00 dollars) The publication appears to give an admirable summary of the law of the subject in the various States of the Union, illustrative cases being quoted when necessary It is of interest that, as in Great Britain, in four of the States and in Hawaii there are statutes providing for the taking of inquisitions by the coroner to determine the cause and origin of fires The taking of *ante-mortem* inquisitions by the coroner is provided for by statute in Connecticut and Rhode Island in the case of persons dangerously injured by criminal act, omission, or carelessness, and likely to die No reforms are formulated or suggested, but the opinion is expressed that the importance of the office of coroner will be greatly enhanced to the community if and when the incumbent of the office is required to be a person skilled in the science of medicine and pathology

#### Announcements

PROF R W WOOD, professor of experimental physics at the Johns Hopkins University, Baltimore, has been elected a foreign member of the Royal Swedish Academy of Sciences in recognition of his researches in the domain of physical optics

THE Council of the Institution of Naval Architects has awarded the premium for the year 1931 to Mr L C Burrill, University of Durham (Armstrong College), for his paper, "Seaworthiness of Collier Types" The premium will be presented at the beginning of the annual general meeting to be held on March 16 at the Royal Society of Arts, John Street, London, W C 2

THE Council of the Institution of Electrical Engineers has made the eleventh award of the Faraday Medal to Sir Oliver Lodge, honorary member of the Institution This medal is awarded not more frequently than once a year, either for notable scientific or industrial achievement in electrical engineering or for conspicuous service rendered to the advancement of electrical science, without restriction as regards nationality, country of residence, or membership of the Institution The Council has elected Mr W. M. Mordey, past president, to be an honorary member of the Institution

THE annual general meeting of the Institute of Metals is to be held in London on March 9 and 10 Whilst the ordinary business of the Institute and the reading of fourteen papers will occupy the first day and the morning of March 10, the second afternoon's session will be devoted to a general discussion on "The Testing of Castings", to be opened by Dr W. Rosenham It is hoped that the discussion of such a practical question will interest all sections of the Institute's membership—those engaged in practical foundry work, engineering users of castings, and testing and investigation experts Visitors are invited also to take part in the discussion, and cards of invitation admitting to the meeting may be obtained on application to the Secretary, Mr G. Shaw Scott, 36 Victoria Street, Westminster, S W 1 A member-

ship election is due to take place on Feb 18 Those elected then will have the privilege of membership, not for the usual twelve months, but for the extended period ending June 30, 1933, and will be able to take part in the proceedings at the March meeting At the annual dinner to be held on March 9, the principal guest will be the Minister of Transport, Mr P. J. Pybus

WITH reference to the article entitled "A New Illumination Device for Microscopy" which appeared in NATURE for Dec 12, 1931, p 1010, we learn from Mr J. E. Barnard that similar objectives with a ring reflector were produced some time ago by Chapman and Aldridge, and were the subject of a British patent In no essential particular did they differ from those recently produced by Messrs. Leitz, who acknowledge the priority of the device of Chapman and Aldridge in their catalogue

CANADA is the leading country in the production of asbestos, most of her supplies being chrysotile A monograph on "Chrysotile Asbestos in Canada", by Mr J. G. Ross, has been published by the Department of Mines, Ottawa The volume, which is finely illustrated, deals with the physical and chemical properties of asbestos, its occurrence in Canada, quarrying and preparation for the market, the manufacture of asbestos products, and the commercial application of asbestos in various industries It concludes with an extensive bibliography of the subject.

THE sixteenth annual of the Paris Academy of Sciences has recently been published It includes a complete list of members, going back to 1795, giving brief biographical particulars, but an innovation occurs this year in the addition to entries of a letter indicating whether the Academy has records of autographs, portraits, medals, and busts of the person in question This year the Academy is paying particular attention to portraits, and it would be glad to receive any information concerning portraits of its members which are not already noted in the annual

PART 20 of the "Catalogue of Indian Insects", issued under the authority of the Government of India, has recently come to hand It deals with the family Alucitidae (Pterophoridae) or 'plume moths', and has been compiled by Mr T. Bainbrigge Fletcher, Imperial entomologist Altogether 78 species are listed with full synonymy, records of their distribution, and keys to the genera We trust that this useful work will be carried to completion notwithstanding the prevailing financial stringency

APPLICATIONS are invited for the following appointments, on or before the dates mentioned —A technical officer in the Admiralty Technical Pool for service in an Admiralty establishment, for work consisting chiefly of design and development in connexion with small precision mechanical and electrical apparatus—The Secretary of the Admiralty (C E Branch), Whitehall, S W 1 (Feb 26) A horticultural superintendent at the Swanley Horticultural College for Women—The Principal, Horticultural College, Swanley, Kent (March 18)

### Letters to the Editor.

[The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, nor to correspond with the writers of, rejected manuscripts intended for this or any other part of NATURE. No notice is taken of anonymous communications.]

#### FitzRoy's Hydrographic Surveys.

WITH reference to the article in NATURE of Dec 26, 1931—pages 1065-1067—on "The Voyage of the *Beagle*", and more especially with reference to the paragraph on page 1068 on FitzRoy in "News and Views", it is not, I think, generally known either how much hydrographical surveying Capt. FitzRoy and his staff carried out during this five years' voyage from 1831 until 1836 or how long this work has stood.

First, it may be mentioned that in 1825 France and England undertook to survey the coasts of South America. The French examined the coasts of Brazil, the English those of Patagonia, Tierra del Fuego, Chile, and Peru.

The surveys carried out by the officers of the *Adventure* and *Beagle* from 1826 to 1831 embraced part of eastern Patagonia south of the Gulf of St. George, the greater part of the Strait of Magellan, Tierra del Fuego, and the west coast between Magellan Strait and Golfo de Penas. Thirty-three charts and forty-five plans of this work were received in the Hydrographic Department.

At the end of 1831, as we know, the *Beagle* again sailed from England to continue the survey and then to run a chain of meridian distances through the Pacific, Indian, and Atlantic Oceans, the ship being supplied with twenty-two chronometers for the purpose.

In 1832 three track charts (Cape Verde Islands to Bahia, etc.) and four plans (ports in the Azores, St. Paul's Rocks, etc.) were received at the Admiralty from the *Beagle*.

In 1833 seven charts of the south-east, south, and south-west coasts of Tierra del Fuego and two plans of parts of the Gulf of Penas were received of surveys made in 1832.

In 1834 nineteen charts and eight plans, also forty views of the surveys carried out in 1833, were received. These embraced the east coast of Patagonia from the south shore of the Rio de la Plata to the Gulf of St. George, including all ports.

In 1835 eleven charts, two track charts, and twelve plans were received, the areas of the surveys being mainly the east coast of Patagonia from the Gulf of St. George to Magellan Strait, the east coast of Tierra del Fuego, and the Falkland Islands, with plans of the ports and anchorages.

In 1837, after the conclusion of the *Beagle's* voyage, Capt. FitzRoy forwarded eighteen charts of the coast of Chile and thirty-four plans, eleven charts of the coast of Peru and eleven sheets of plans, embracing the whole coast from the Chonos Archipelago, 47° S, to the Guayaquil River, 3° S, and including all the ports and anchorages along the coast, also six charts and eight plans of the Galapagos Islands, and three charts and one plan of other islands in the Pacific Ocean.

It will thus be seen that during the period of this voyage no less than eighty-two coastal sheets, eighty plans of harbours, and forty views were received in the Hydrographic Department of the Admiralty from FitzRoy's surveys.

These surveys of the coasts of South America were used for the production of the Admiralty charts and

are mostly still the foundation of the present-day charts of this area.

The Argentine Government surveys have superseded them between the Rio de la Plata and the Gulf of St. George, but the charts of the east coast of Patagonia southwards, with the exception of the plans of the ports, still incorporate these surveys. The charts of Tierra del Fuego are also largely founded on the *Beagle's* work. In Magellan Strait the larger portion of the *Beagle's* work has been superseded, the Main Strait being taken from later British and foreign government surveys, but the adjacent waters are still partly from the *Beagle's* surveys.

For the west coast of South America from Magellan Strait to about latitude 40° S, that is, including all the Chonos Archipelago, Chiloe Island, etc., our Admiralty charts are compiled from the Chilean Government charts, and thence northwards to Valparaiso—approximate latitude 33° S—FitzRoy's surveys have been modified by later Chilean and other work, whilst only a few of our plans of Chilean ports and anchorages are now produced from the results of FitzRoy's work.

However, northwards from Valparaiso to the River Guayaquil, all the Admiralty charts of the Chilean coast and of all the Peruvian coast are from Capt. FitzRoy's surveys, and almost all the plans of Peruvian ports likewise.

This very large amount of work must have called for the greatest energy and zeal on the part of Capt. FitzRoy, his officers, and ship's company, more especially when one bears in mind the fact that these surveys were all carried out either from boats or from the ship under sail and with appliances which nowadays we would consider most crude.

Finally, as regards the chain of meridian distances round the world, it is recorded that these exceeded twenty-four hours by thirty-three seconds only, in a period of five years.

#### Specific Heats of the Diatomic Gases.

THE marked disagreement between the specific heats of the diatomic gases as found by sound velocity measurements and those calculated on theoretical grounds has for long been a source of perplexity to statistical mechanists, especially in view of the apparently simple nature of the assumptions required in the calculation. The easiest of these assumptions to attack would seem to be that of complete equilibrium between the various degrees of freedom of the molecule as the sound waves pass.

In two recent papers<sup>1</sup> Kneser has shown, by means of sound velocity measurements, that there is a lag in the transfer of energy between the vibrations of the CO<sub>2</sub> molecule and the other degrees of freedom much greater than that which has been hitherto suspected. In fact, he found that the period of relaxation for the vibration concerned was of the order of 10<sup>-5</sup> of a second, in place of the usually assumed period of the order of 10<sup>-10</sup> of a second. Now, if one admits a value of 10<sup>-5</sup> of a second for CO<sub>2</sub>, why should one not suppose that the period for oxygen may be of the order of 10<sup>-4</sup> of a second? Unless we are to disregard the sound velocity results *in toto*, we must make some fundamental alteration to the theory, and this seems to be the easiest to make. I find that the results of

Shilling and Partington<sup>2</sup> for oxygen and nitrogen can be accounted for if we assume the following values for the relaxation period of the vibrations

| Temperature | Relaxation Period in Sec |                       | Transparency Coefficient |          |
|-------------|--------------------------|-----------------------|--------------------------|----------|
|             | Oxygen                   | Nitrogen              | Oxygen                   | Nitrogen |
| 0° C        |                          |                       | 370                      | 8600     |
| 300° C      | $1.0 \times 10^{-4}$     |                       | 19.5                     | 58       |
| 600°        | 1.2                      | $0.88 \times 10^{-4}$ | 11.1                     | 20       |
| 900°        | 1.1                      | 0.92                  | 9.4                      | 12.5     |
| 1200°       | 1.0                      |                       | 7.9                      | 10.3     |

\* At room temperature the vibration comes in so little that the expected effect is smaller than the probable errors of the sound velocity determinations, and I have not included values for the relaxation period for 0° C.

If the period really is as long as this, there must be considerable absorption of the sound energy at the frequency at which the velocity is varying most rapidly. This frequency would be round about 1400 vibrations per second for both oxygen and nitrogen, according to the above results, and in the table are given values which I have calculated for the number of wave-lengths which the sound should travel before the amplitude is reduced to  $1/e$  times its initial value. It will be seen that the effect should be easily measurable at the higher temperatures, but is slight at room temperatures, so that the measurements which have been carried out at these temperatures do not tell us much.

The obvious methods of attack are the measurement at the higher temperatures of the velocity of sound over a considerable range of frequencies, and of the absorption of the sound energy. A more direct, if experimentally difficult, method depends upon photographing the ultra-violet absorption spectrum of oxygen as it is coming out of a cylinder at high pressure and temperature and noting the relative intensities of the various lines and bands. I hope to carry out this experiment shortly, and will not say more about it here.

It may be pointed out that determinations of the specific heat of oxygen carried out by means of a flow method,<sup>3</sup> in which the heating of the gas took about a quarter of a second, gave results nearly in agreement with theory, whilst the adiabatic expansion experiments of Eucken and Lude,<sup>4</sup> where the cooling was more rapid, gave results intermediate between the theory and the sound velocity results.

Finally, it is interesting to refer to a paper by Zener,<sup>5</sup> in which he points the way to calculation on wave-mechanical principles of the chance that a molecule will give up its vibrational energy in a collision. At the end of the paper he states that "for a typical case of collisions between diatomic molecules, where one molecule has one quantum of vibrational energy", the chance of transfer in a given collision is about  $2 \times 10^{-5}$  at 0° C. This we may compare with the value for the probability of the transformation of the vibrational energy (which should be considerably less) calculated from the relaxation period given above for oxygen at 600° C, which is  $0.5 \times 10^{-5}$ .

### Surface Convection and the Distribution of Temperature near a Heated Surface.

LAST summer we took some temperature measurements under the steady conditions prevailing at the epoch of diurnal maximum temperature above an asphalted road where inferior mirage could be seen on any clear day. The temperature variation with height above a hot surface was shortly afterwards measured also in the laboratory. The lapse-rates were of the order of 20°-30° C per cm in the first centimetre, and of the order of 1°-2° C per cm at higher levels near a heated surface. The observations showed that there was (1) a 'skin layer' within the first centimetre, and (2) a 'surface layer' extending up to about 20 cm above the hot surface. The variation of temperature above these layers is practically negligible compared to the much larger variations below.

Taking into account the balance in an elementary layer between the heat received by convection processes and the net loss of heat by radiative processes, the following expression was derived

$$\phi = \phi_0 \frac{\sinh \alpha(h-z)}{\sinh \alpha h},$$

where  $\phi$  is the variable part of the temperature,  $\phi_0$  and  $h$  are constants, and  $\alpha$  is a constant equal to  $\sqrt{16\sigma\theta_0^3/k}$  involving the effective absorption coefficient of water

FIG 1

vapour  $a$ , the Stefan-Boltzmann constant  $\sigma$ , the convective conductivity  $k$ , and  $\theta_0$  the constant part of temperature. The temperature distribution observed above the road as well as in the laboratory experiments agreed with the above expression.

The nature of the turbulence near a hot surface was studied experimentally by us in detail. The space above a heated surface kept inside a smoke chamber provided with observational glass windows was illuminated by a concentrated beam of sunlight. Ammonium chloride or sulphur fumes were used. It was found that, just as in Aitken's and Lodge's experiments, there was a dark, dust-free layer above

the hot surface. The heated dust-free air was found to shoot up into several tongues of ascending air, these dark columns which conveyed the heat upwards travelled several centimetres upwards, but while their base near the hot surface was 1.5-2.5 cm broad, their width very rapidly decreased towards the apex. The dark columns develop and move about in a random manner. The corresponding downward movements of the cold air can also be observed. These movements are associated with vortices excited by the uprush of the hot air. The photographs reproduced in Fig. 1 give a rough idea of this phenomenon. In the permanent dark space above the surface it is likely that the heat conductivity is of the order of molecular conductivity, as suggested by the work of Prandtl and Langmuir.

Our results are being published in two articles in the *Indian Journal of Physics*, Calcutta

### Gill-Morell and Barkhausen-Kurz Oscillations

In the production of ultra-high-frequency oscillations by means of triodes with positive grid, it has been apparent that there exist two distinct types, Gill-Morell oscillations, the frequency of which depends solely on the external circuit of the valve, and Barkhausen-Kurz oscillations, the frequency of which

Fig. 1—Apparatus for production of electron oscillations.  $L$ ,  $L$ , Lecher wires,  $C_1$ , movable bridge,  $C_2$ , blocking condenser

depends mainly on the operating voltages. In 1928 Hollmann<sup>1</sup> obtained results tending to indicate that the Gill-Morell oscillations are a modified form of Barkhausen-Kurz oscillations and are invariably of higher frequency.

In the course of an investigation into the effect of

Fig. 2—Variation of wave-length with bridge position

varying the emission current, I have found that with one particular valve arranged in the normal way (Fig. 1) not only were Hollmann's results obtainable, but in addition true Gill-Morell oscillations as well. For most positions of the tuning bridge of the external circuit the value of the emission current decides

which type of oscillation is maintained. For higher values of grid voltage there are two values of emission current for optimum maintenance of the Barkhausen-Kurz oscillations, the wave-length for the lower value of emission being slightly shorter than that for the higher value. This agrees with results recently published by Moore<sup>2</sup>.

A typical set of observations on the wave-lengths maintained at various bridge positions is shown in Fig. 2. For each wave-length the emission was adjusted for optimum maintenance. It will be seen that the Gill-Morell oscillations extend on both sides of the Barkhausen-Kurz range. The amplitude of both types of oscillations, as measured by the increase of plate current, reaches a maximum at points A, when the maintained wave-lengths of the two regimes approach equality.

It is hoped to publish further details of this investigation shortly.

### Air Column Resonances and Symmetrical Modes of Truncated Conical Shells (Loud Speaker Diaphragms).

In investigating modes of vibration of truncated conical shells of paper, aluminium, and glass, the frequency of a certain resonance group was found to be dependent upon the dimensions only. Table 1 gives some of the data obtained when the cones were driven in a large, highly damped room, by a coil 2.5 cm in radius wound on a short paper tube.

1. AIR COLUMN RESONANCES

| Material and Thickness (cm.)       | Radn (cm.) and Apical Angle | Main Frequency (~) |
|------------------------------------|-----------------------------|--------------------|
| Paper, $2.1 \times 10^{-2}$        | 12.2, 2.5, $90^\circ$       | 900                |
| " "                                | 12.2, 2.5, $60^\circ$       | 650                |
| " "                                | 12.2, 2.5, $30^\circ$       | 350                |
| Aluminium, $8 \times 10^{-2}$      | 19, 2.5, $90^\circ$         | 570                |
| Glass, about $1.65 \times 10^{-1}$ | 12.7, 1.4, $107^\circ$      | 1100               |

The resonance is mainly due to the air column within the cone, the source of vibration being the cone itself. (The air column is stopped by the magnet at the coil end, excepting for leakage between the coil and magnet.) The problem differs, therefore, from that of a simple source (of small magnitude compared with the wave-length), situated somewhere in the air column.

The main frequency is given approximately by the formula

$$f = c/2(l + ka),$$

where  $c$  is velocity of sound in free air,  $l$  is axial length of cone plus part of paper tube,  $a$  is radius of open end, and  $k$  is an end correction factor varying from 0.6 to 0.8. This result is reminiscent of that of Wheatstone, who found (about 1870) that the fundamental of a small angle cone is twice that of a cylinder of equal length. Here the source was a tuning-fork near the mouth, which is different from the present case.

Experiments on the symmetrical modes of conical shells show that they occur at much closer frequency intervals than those of a circular disc.

The most definite results have been obtained with an ordinary glass lamp-shade

2 GLASS CONE, RADII 12.7 CM, 1.4 CM  
 $\psi = 107^\circ$ ,  $t = 1.65$  MM (ABOUT) DRIVING COIL 2.5 CM RADIUS

| Nodal Pattern | Frequency (~) | Rel Output (approx) |
|---------------|---------------|---------------------|
| One circle    | 4500          | 10                  |
| Two circles   | 5700          | 44                  |
| Three circles | 7500          | 19                  |

The greatest output corresponds to two nodal circles, and the three peaks are very sharp indeed. With paper cones the peaks are not clearly defined, especially if the mass of the driving coil is small.<sup>1</sup> In fact, over a band of frequencies the output changes but little. The definition increases with the thickness of the material.

These results indicate that the 900-cycle resonances described in a recent paper<sup>1</sup> are mainly due to the air column, whilst those around 2300 cycles pertain to the symmetrical modes. The relative importance of the air column resonances obviously increases with decrease in the mass of the diaphragm, since the amplitude is greater, for example, for paper they are about 0.5 that at 2300 cycles, whilst for the heavy glass cone they are negligible.

#### Propagation of Hertzian Waves in Electronic Gas under the Influence of a Magnetic Field

WHEN an electromagnetic wave of frequency  $\nu$  travels through a medium consisting of free electrons ( $e/m = 1.78 \times 10^{-7}$  e.m.u.) under the influence of a

magnetic field  $\vec{H}$  of suitable direction and strength ( $H = 2\pi m\nu/e$ ), an irregularity in the propagation of the wave is predicted from the fact that the electrons, under the influence of the field, are caused to move on closed orbits with the same frequency as that of the incident wave, and therefore they are tuned to resonance and absorb a part of the energy of the wave. To this fact may be attributed the irregularity in the propagation of the wave of 214 metres wave-length ( $\nu = 1.4 \times 10^6$  hertz) travelling in the earth's magnetic field ( $H = 0.5$  gauss). This irregularity has been predicted by Appleton<sup>1</sup> and found by Taylor<sup>2</sup> in experiments made on reception from stations radiating waves of the same power and of a wave-length between 15 metres and 600 metres.

Since very short continuous waves may be obtained in the laboratory by thermionic valves, it is possible to confirm the phenomenon by direct experiment. I have used 18 cm waves, produced by an oscillator of Pierret<sup>3</sup> type. As a receiver I have used a short tuned antenna in which a galena rectifier, connected with a sensitive galvanometer, is inserted. The experimental arrangement allows the wave from the oscillator to pass through the anode filament space of a diode placed inside a coil producing the magnetic field, the filament is arranged along the lines of force. Under the combined influence of the magnetic and the electric field, due to anode potential, the anodic space is filled with almost circular electronic orbits lying in planes perpendicular to the lines of force. Special precautions were taken to lessen the remarkable diffraction phenomena and to prevent the diode itself oscillating in the magnetic field.

Lighting the diode causes a distinct diminution in the galvanometer deflexion due to the arriving wave, when the strength of the magnetic field is about 600 gauss. The effect disappears at values of field strength a little greater or smaller than the above mentioned, which corresponds, to a good approximation, to the value (562.7 gauss) theoretically necessary to give to the electrons, rotating in the orbits inside the diode, the frequency of  $1.6 \times 10^9$  hertz corresponding to a wave-length of 18 cm.

I have found that the observed effect

(a) Is proportional to the number of the absorbing orbits produced inside the diode,

(b) Increases linearly with the energy of the incident wave,

(c) Accompanies the incident vibration, whatever may be the plane in which this vibration is polarised with reference to the electronic orbits inside the diode.

Experiments are being carried on in order to confirm directly some consequences suggested by the theory on propagation of Hertzian waves in an ionised medium under the influence of a magnetic field.

I am indebted to Prof. Q. Majorana for his interest and advice in connexion with this investigation.

#### A Method of High-Frequency Stroboscopy

AN extension of the principle used in the preliminary investigations on the modes of vibration of a quartz crystal, as indicated in a previous note,<sup>1</sup> has enabled the observance of the density changes within the crystal to be carried out stroboscopically.

The apparatus and the general arrangement is as previously described, with the exceptions (a) that two crystals are used, and (b) that a mechanical interrupter is arranged to intercept the light-beam just in front of the image. The two crystals in the present case are practically identical, their frequencies corresponding to Fig. 1 in the previous note, being approximately 88 kc, and 88 kc and 42 c respectively.

By adjusting both crystals in the manner described previously, one in each light-beam, and also by so placing them that they are superimposed optically, it is possible, when both crystals are oscillating, to adjust the speed of the interrupter (to, say, 40 interruptions a second) so that the narrow dark band normally seen changes width cyclically. Similarly, when other modes of vibration are used the periodic variations in density through various parts of the crystal may be readily followed at a convenient speed.

Not only may this method be used successfully for the density changes within the crystal, but it may also be applied to the radiated sound-field, this is effected by the superposition of the two sound-fields in exactly the same manner as the crystals were superimposed above. Again, by correct interruption, it is possible to see the brilliant striations of half-wave spacing progressing at slow speed from the active face of the crystal.

Furthermore, it is not necessary to limit oneself to two crystals exactly similar in dimensions when observing the sound-fields, as a frequency difference of up to 1 kc may be readily corrected by a suitably designed interrupter, thus two very dissimilar crystals with resonant frequencies of 103.6 kc and 104.5 kc respectively have been successfully used as sources of the two sound-fields.

It is clear that the method indicated in the previous note will produce, by means of density variations, the same result as was obtained by Kerr Grant<sup>2</sup> by means of optical rotation, namely, the high-frequency interruption of light. Although the resultant light in this case has not been examined with a rotating mirror, it is obvious from the stroboscopic result obtained that such high-frequency interruption is occurring.

### Hyperfine Structure of the Mercury Line $\lambda 4916$ .

IN a recent note,<sup>1</sup> Venkatesachar and Sebaiya have repeated their measurements on the hyperfine structure of the mercury arc line  $\lambda 4916$  and again find a coarse octet structure as before. This contradicts the narrow quintet structure previously reported by me<sup>2</sup> and by Hansen<sup>3</sup>. Recently, two further reports have appeared, namely, that of Murakawa<sup>4</sup> and of Schuler and Keyston<sup>5</sup>. The structures given by the various observers (in  $\text{cm}^{-1} \times 10^{-3}$ ) are shown in the accompanying table, the central component being given the intensity 30 in all cases.

| T.      | H        | M       | SK      | VS       |
|---------|----------|---------|---------|----------|
| 128 (2) | 121 (15) | 125 (3) | 125 (2) | 612 (3)  |
| 62 (3)  | 66 (9)   | 60 (3)  | 66 (3)  | 364 (6)  |
| 0 (30)  | 0 (30)   | 0 (30)  | 0 (30)  | 124 (9)  |
| 55 (4)  | 56 (12)  | 55 (7)  | 56 (5)  | 0 (30)   |
| 98 (1)  | 98 (6)   | 96 (1)  | 99 (1)  | 83 (6)   |
|         |          |         |         | 240 (3)  |
|         |          |         |         | 306 (15) |
|         |          |         |         | 572 (6)  |

The sources used by the different observers are as follows

T.—Tolansky—high frequency electrodeless discharge

H.—Hansen—water-cooled arc (Lummer lamp)

M.—Murakawa—source unspecified

SK.—Schuler and Keyston—hollow cathode discharge

VS.—Venkatesachar and Sebaiya—branched arc

The first four agree extremely well, there being intensity deviations only in Hansen's data.

According to the analysis given by Murakawa and by Schuler and Keyston, only the narrow quintet should be expected. It is very probable that the components 124, 0, 83 of Venkatesachar and Sebaiya are in reality the five components of the other observers, appearing as a triplet when unresolved. It seems quite certain, when the various sources are considered, that the quintet structure is the normal structure of the arc line. The 'branched arc', then, appears to give the normal structure together with five other strong components. If this coarse structure is correct, it can only be due to the source. Such an unusual dependence of fine structure upon source is quite exceptional. Collins<sup>6</sup> found unusual resonance fine structure in  $\lambda 5461$  in mercury, but in this case components were missing, whereas  $\lambda 4916$  appears to give new components in addition to the arc structure. The dependence of the fine structure of  $\lambda 4916$  upon the source employed is worth further investigation.

### Saxifrage Crosses

DR F. W. SANSOME<sup>1</sup> questions the assertion made by me<sup>2</sup> that *Saxifraga potternensis* arose from a doubling of the chromosome complement at the semi-heterotype divisions in the  $F_1$  plant of the cross *S. rosacea*  $\times$  *S. granulata*, and offers the alternative suggestion that the  $F_1$  plant was wholly or in part tetraploid in its somatic tissue.

Collections of cytological material were made in the summer of 1931 from  $F_1$  generation plants, as well as from certain reciprocal and back-crosses. Unfortunately, time does not permit a detailed study of all this very interesting material available as a result of breeding work at the Potterne Biological Station, but sufficient re-examinations of  $F_1$  plants have been made to confirm the opinion first put forward in 1930.

As originally stated, all pollen mother cells studied had the parental chromosome number, with very irregular divisions and marked lagging of univalents on the way to the poles during the heterotype division. There is no doubt about the presence of a certain proportion of non-reduction, either by cancellation of the meiotic division or by the fusion later of homotype plates. The general proportion of healthy pollen grains was in agreement with the number of non-reduction divisions noted in the same flower, and would be, in my opinion, sufficient to permit of a reasonable seed production.

Dr Sansome's suggested method of origin implies that the behaviour at meiosis and the general fertility (percentage of good pollen and quantity of seed produced) in the flowers of the  $F_1$  generation should be more or less comparable with that of the  $F_2$  plants, as is the case with the examples quoted in his table from the genera *Nicotiana*, *Primula*, and *Solanum*. No evidence to support this contention was found in the material, nor was any part of the plants examined tetraploid in its somatic cells.

In the absence of data regarding the actual seed production of the  $F_1$  plant as compared with the  $F_2$  plant, and of definite evidence showing that all the seed which gave rise to *S. potternensis* came from one (tetraploid) part of the  $F_1$  plant, there does not appear yet to be any good reason why my interpretation should not be feasible.

### A New Autotrophic Bacterium which Oxidises Ammonia directly to Nitrate and Decomposes Petroleum.

IN connexion with the studies of the senior writer<sup>1</sup> on living micro-organisms in ancient rocks, an attempt was made to determine whether or not old materials other than rocks harbour living micro-organisms. Among such materials studied was petroleum. An attempt to find cellulose-destroying organisms in petroleum by inoculating the latter into a cellulose medium yielded an organism which apparently has no power to decompose cellulose but has an extraordinary physiology. It was isolated from petroleum derived from a well more than 8700 feet deep, owned by the Standard Oil Company of California.

The organism is a coccus or cocco-bacillus, variable in size and somewhat so in shape. It grows very well under strictly autotrophic conditions in an inorganic salt medium with ammonium sulphate or

potassium nitrate as the source of nitrogen. It oxidises ammonia directly to nitrate without passing it through the intermediate step of nitrite formation as do the group of bacteria known as nitrifying bacteria. The nitrate producing power, moreover, is manifest very quickly under such conditions—much more so than is true of the nitrifying bacteria. It is apparently a facultative aerobe. In addition, it possesses the power of completely decomposing petroleum without apparent gas formation aside from the end-product, gaseous carbon dioxide.

We have noticed in the literature two or three cases in which organisms isolated from soil were described as possessing the power to oxidise ammonia directly to nitrate. These reports have never been confirmed, and the other powers attributed to our organism above have not been indicated in such earlier reports. A full account of our investigation with this remarkable organism will be published elsewhere, together with a comparison of our results with those of Kaserer, Sohngen, and others whose work has a bearing on the subject under discussion.

### Periodic Precipitation.

PROF. J. W. MCBAIN has directed attention<sup>1</sup> to the very beautiful experiments carried out by Dr. H. W. Morse, an account of which was published last year in the *Journal of Physical Chemistry*, together with thirty-two remarkable photomicrographs illustrating various types of periodic precipitation in aqueous solution in the entire absence of gels. As Morse points out, it follows that "no gel is necessary for periodic precipitation." He further states that preliminary measurements indicate that ring formation in water follows the same rule as in gels, namely, that the ratio  $\frac{d_3 - d_2}{d_2 - d_1} = k$ , where  $k$  is a

constant ratio of increasing distance between neighbouring rings. The two phenomena thus appear to be due to essentially the same cause.

Morse suggests as an explanation for periodicity of precipitation in aqueous solutions that there is a rapid change at the point where the ring appears, due principally to the diffusion of the reacting substance, resulting first in saturation with the substance of the precipitate, then in a rapid increase in the degree of supersaturation, and finally in 'release' of supersaturation, this release taking place in the absence of nuclei of the solid phase.

In 1922, when studying periodic precipitation of silver chromate in gelatin, we suggested<sup>2</sup> that the distance between successive rings is determined by the difference between the rates of diffusion and of precipitation in the gel; we also showed that protective colloids tend to retard the velocity of such reactions as involve a change of state. Morse's experiments would appear, therefore, to support our view that the main effect of the gel is to retard the 'release' of supersaturation and thus to enhance the relative effect of diffusion, this resulting in an increase in the distance between successive rings, other things being equal, over that in the absence of the gel.

### Photoreduction of Carbonic Acid, Bicarbonates, and Carbonates to Formaldehyde.

IN these laboratories we have been carrying on experiments on photosynthesis in tropical sunlight for a number of years<sup>1</sup>. We have been able to obtain formaldehyde by the exposure of solutions of carbonic acid and bicarbonates to tropical sunlight in presence of various inorganic and organic photocatalysts.

Now we have been able to reduce carbonic acid, carbonates, and bicarbonates to formaldehyde by means of metallic magnesium and zinc. The yield of formaldehyde in light is considerably greater than that in the dark. Contrary to the observations of Fenton,<sup>2</sup> we could not detect any formic acid either in sunlight or in the dark. It should be pointed out here that Fenton carried on his experiments only in the dark, and obtained formic acid as the main product by the action of an amalgamated magnesium rod on carbonic acid. The chief importance of these experiments consists in the fact that the yield of formaldehyde obtained in our photoreduction experiments is much greater than hitherto obtained by any previous worker. Moreover, we have been able to increase the yield further by the addition of photosensitisers like zinc oxide.

We have found that the photoreduction of these substances can also be effected by ferrous carbonate. These experiments lend considerable support to the view previously announced by us that chlorophyll, besides being an optical sensitiser, also acts as a reducing agent.

From 100 c.c. of a 10 per cent solution of potassium bicarbonate with 1 gram of powdered magnesium in presence of zinc oxide after an exposure of five and a half hours to sunlight, the yield of formaldehyde is 0.0045 gm. No reducing sugar could be detected in these photoreduction experiments with powdered magnesium.

Further work in this direction is in progress.

### Helmholtz or Kelvin Cloud Waves.

IT is of some historical interest to notice that the habitual use of the phrase 'Helmholtz Waves' to describe parallel rolls of cloud produced in the transverse direction by a wind in an upper region blowing over stationary air below is only partly justified, and many students of hydrodynamics are unaware of Kelvin's work in this connexion. It is true that Helmholtz in 1889<sup>1</sup> worked out the theory of these waves and applied it to clouds. But, as he pointed out in a footnote, the general theory of such waves between two media in relative motion had been given by Kelvin in 1871<sup>2</sup>, so while the meteorological application was due to Helmholtz, it was Kelvin who provided the essential hydrodynamical explanation.

## Research Items.

**Ethnic Pathology**—Some interesting personal observations are recorded by Prof V Suk in the course of a discussion of possible lines of research in ethnic pathology in *Pub* No 141 of the Faculty of Science, of the Masaryk University, Brno. In dealing with the incidence of tuberculosis among the Eskimo of the north coast of Labrador, he states that in examining about a hundred children, pure and mixed, the cutaneous tuberculin test gave 9.8 per cent positive reactions among Eskimo children of pure blood (51 cases) and 56.2 per cent among mixed breeds (32 cases), that is, an overwhelming preponderance of infection among those who live in an Eskimo climate on European food such as tinned meat, tinned margarine and bad flour, as opposed to the Eskimo diet of raw seal blood, meat, and entrails. Yet on the other hand, tuberculosis is very fatal to the Eskimos when once they are attacked. They succumb in a few weeks. Among them it is a new disease, whereas among Europeans it is of long standing, progress of the disease is normally slow, and evidently partial immunity has been established. Prof Suk has also some interesting observations to make on the subject of cretinism. He finds that in cretinism characteristic racial features may be blurred beyond recognition and 'cosmopolitan' cretinous features established. Thus one case in Carpathian Ruthenia he found, to his surprise, was not a Ruthenian but a Jewess, while in other cases in which several cretins occurred in one family, there were different degrees of development in which particular racial features were blurred to a varied extent. In discussing other lines of investigation, Prof Suk points out the need for inquiry not only among primitive peoples but also among the civilised. Relatively little precise and well documented evidence is available for the incidence of disease in nordic, alpine, and Mediterranean races.

**The Flight-speed of British Birds**—Further data supplementing the records by T H Harrison (*NATURE*, Oct 3, 1931, p 586) have been published (*Brit Birds*, Jan). The records were made by B B Roberts from a motor car with reliable speedometers, when there was no appreciable wind and when at least sixty yards and usually more than a hundred yards had been travelled parallel to the birds' course. The fastest of the times was 51 miles per hour recorded for a wood-pigeon, chased up from its average of 47 m p h, which was exactly the speed of a red grouse, the slowest, a striking record, the 15 m p h of a common tern. On the whole, wherever they can be compared, the readings of the two independent observers are very similar. According to one, the rook ranges from 24 to 35 m p h, according to the other, 27 to 35 m p h, the starling, 25 to 30.5 and 28 to 41, the chaffinch, 25 to 29 and 27 to 35, or of the more rapid fliers, the wood-pigeon, 27 to 51 and 23 to 47. The one migration record of this series, that of a flock of lapwings, indicates, as the former series suggested, that migration flight is distinctly more rapid than normal flight, for the lapwing's average was only 28.33 m p h, whereas the flock travelled at 41 m p h. The result of the records as a whole is to confirm the impression that the earlier notions about the speed of bird flight were much exaggerated.

**Regulation of the Blood in Fishes**—In fresh water a fish, because of the salt content of its blood, is osmotically superior to its environment, so that it excretes a solution more dilute than its blood—hypotonic excretion. In salt water the condition is reversed and

the fish must get rid of a solution more concentrated than its blood—hypertonic excretion (Homer W Smith, *Copeia*, Dec 1931, p 147). The vertebrate kidney at any stage lower than mammals is incapable of excreting a hypertonic urine, and, amongst fishes, teleosts and elasmobranchs have solved the problem in two different ways. The teleost 'drinks' sea water, and absorbs the water and most of the salts from the gut. The salts it excretes for the most part extrarenally (by the gills), thus leaving water osmotically free for the formation of urine in compliance with the osmotic limitations of its kidneys. The elasmobranch does not require to drink sea water, since it conserves urea by reabsorbing it from the urine, so that a natural uremia results, the urea concentration of the blood rising to as much as 2.5 per cent. The raising of the osmotic pressure of the blood above that of sea water means that water is directly absorbed, probably through the gill membranes, while salts are partially or wholly excluded. So in the sea the teleost retains for itself the relative balance with its environment which is characteristic of fish life in fresh waters.

**Composition of the Body Fluid of Animals**—C F A Pantin has discussed (*Biol Rev*, vol 6, pp 459-481, 1931) not only the origin of the body fluids in animals, then approximate similarity in composition and relation to sea water, but also the mechanism whereby in some organisms the composition of the body fluid may be maintained, though quite different from that of the external solution. It is shown that there are all gradations, from the simplest case, in which the body fluid closely resembles the external solution (sea water) both with regard to total osmotic concentration and to the relative proportion of the salts, to the more complex, in which, not only does the composition deviate from that of sea water (particularly in a tendency to increased potassium and decreased magnesium and sulphate concentrations), but also the total osmotic concentration no longer equals that of the surrounding medium and an increased osmotic independence of the environment is obtained. Both the osmotic gradients and the ionic concentration gradients are discussed and interpreted as actively maintained by a steady state in which work is done, and are not regarded as determined by equilibrium conditions.

**Larvæ of Leaf-mining Beetles**—In the course of his studies "On the Structure of Larvæ of Hispine Beetles" (*Proc Zool Soc*, London, part 3, 1931, pp 1137-1162), Mr S Maulik directs attention to the fact that the conception of an adult insect as being the end-stage or completion of a species is pure presumption. He looks upon the adult as but one stage in a continuous cycle. "While", he says, "the adult stage is being formed, the next stage is also taking form, and so the observed sequence of events goes on." The view that the "adult stage is the end result to which the organism is attaining" has directed attention away from the study of larval characters. Nevertheless, he points out that the larvæ described in this paper are generally more adaptable, and therefore their characters more plastic, so that in doubtful cases of relationship more reliance should be placed on adult characters. This is the generally accepted view in other groups of insects, but Mr Maulik thinks it should not be accepted in any group until it has been proved in that group also. Altogether seven species of larvæ are described in detail, all of them beautifully figured by Mr Terzi,

in two of them the complete life history is worked out. The special adaptation of the spiracular organs of these larvæ to the leaf-mining habit is particularly interesting.

**Stone Cells of Pear Fruits**—Stone cells were described by Nehemiah Grew so early as 1682, but their practical significance from the point of view of fruit quality has only just been studied by J. W. Crist and L. P. Batjer (*Tech. Bull.* No. 113, Michigan State College Agricultural Experiment Station "The Stone Cells of Pear Fruits, especially the Kieffer Pear", pp. 55, 1931). The authors have tried the effect of various cultural treatments, propagation influences, size and vigour of tree, and different times and methods of ripening on the number of stone cells present in the pear fruit. They have been unable to reduce the number of stone cells by any such treatments, and conclude that improvement of the Kieffer pear must be through genetics. They publish some striking photographs showing varietal differences in stone cell content, and have made chemical studies of the fruits. There is a difference in the seasonal hydrogen ion concentration of the tissue of Kieffer and of Bartlett pears which seems to bear some relation to the stone cell content. The former is relatively more acid than the latter in May, but towards the end of June the position is reversed. A similar reversal in the number of stone cells is also observed, Bartlett having more than Kieffer in May and less in June.

**Recent Scottish Earthquakes**—Dr. G. W. Tyrrell has published a very valuable account of four earthquakes felt in Scotland in 1925 and 1927 (*Trans. Glasgow Geol. Soc.*, vol. 19, pp. 1-41, 1931). The Oban earthquake of Dec. 23, 1925, is of great interest from its probable connexion with the Great Glen fault, along which most of the strongest earthquakes in the country originate. This shock was of intensity 6 (Rossi-Forel scale). The boundary of the disturbed area cannot be traced with exactness. Excluding isolated records, it appears to have contained about four thousand square miles, though it may have been four times as much. The most interesting of the other earthquakes was the North Sea earthquake of Jan. 24, 1927, one of the strongest ever felt in Scotland. The disturbed area included practically the whole of that country with the exception of the Western Islands. Within a small district near Peterhead the intensity was 7. The shock was also felt at Warkworth in Northumberland, and over a large district in southern Norway. The epicentre, as determined from seismographic records by Dr. N. H. Kolderup, lay in lat.  $59^{\circ}$  N, long.  $5^{\circ}$  E, that is, under the North Sea not far from the coast of Norway, between Haugesund and Stavanger. The focus is thus asymmetrical with reference to the isoseismal lines, and this raises the question whether there may not have been a second focus nearer the Scottish coast, for the shock in Great Britain was distinctly double.

**Oilfields of Zante**—Zante is the southernmost of the Ionian Islands, and its association with petroleum goes back a long way in history. Both Pliny and Herodotus have referred in their writings to the 'pitch' of the island, and local tradition assigns the ancient well of Herodotus to this place. Occurrences of oil in the island have been described by Redwood, and Dr. A. Wade gave the Institution of Petroleum Technologists an interesting account of its geology and ancient oilfields on Dec. 8 last. The island may broadly be regarded as a remnant of a rectangular block of resistant Cretaceous Eocene limestone orientated north-west-south-east, tilted slightly to the north-east, overlain by Miocene and Pliocene sediments.

The Miocene deposits include gypsiferous deposits with associated clays and bituminous marls, there are also nummulitic limestones and bituminous limestones of Eocene age. The author leans to the view that the oil originated in the Miocene series in which it occurs, but he also points out that there may be, by analogy with the bituminous limestones of Cretaceous-Eocene age in the Grecian archipelago, deeper and totally independent oil-bearing strata in the underlying rocks of that age in the island. Actually the so-called 'pitch' of Zante is a very heavy crude oil, and Herodotus's 'pitch' well at Keri Marsh was evidently a seepage of this material. The well is a brackish water spring carrying oil and inflammable gas, stimulated by the latter, several unsuccessful attempts have in the past been made to obtain the oil in commercial quantity, failure being due, according to the author, to lack of knowledge and inexperience on the part of the early operators. Results of physical examinations of two samples indicate that the oil is of asphaltic base, specific gravity 1.010-1.0046, about 1 per cent petrol, 14 per cent kerosene, 30-40 per cent lubricating oil, and 40-50 per cent asphalt, there is apparently some 6 per cent of sulphur.

**Aerial Phototriangulation**—One of the difficulties in measuring the arc of meridian which passes through the Balkan peninsula and eastern Africa is to bridge the gap afforded by the Mediterranean. The chief problem lies between Crete and Egypt, a distance of about two hundred miles at least. The heights on the opposite sites, despite the considerable altitudes in Crete, are not sufficiently great to allow sights to be taken across the sea. An ingenious method is suggested by Prof. D. Lampadariou (*C. R. Acad. Athènes*, April 6, 1931). He suggests the use of three known points in Crete and another three in Africa. From these points brilliant lights would be shown and recorded simultaneously on one plate exposed by an aeroplane roughly midway between the two coasts. This would enable six horizontal angles to be fixed from the developed plate. In fact, the aeroplane would thus serve as an intermediate station between Crete and Africa. Prof. Lampadariou explains in his paper the apparatus required and the necessary precautions to be taken.

**Measurement of High Temperatures**—The accuracy and reproducibility of the high temperature scales in use in various laboratories appear very clearly in an account of an intercomparison of scales given by Dr. W. E. Forsythe, of the Lamp Development Laboratory of the American General Electric Co., in the second September issue of the *Physical Review*. A number of tungsten lamps were carefully aged and calibrated at Nela Park, and were then sent to the Physikalisches-Technische Reichsanstalt in Berlin, Philips' lamp works in Eindhoven, the Laboratoire Central in Paris, and the Osram works in Berlin. In each place the temperatures of the lamps were measured for specified currents with a disappearing filament optical pyrometer, using red glass as the monochromatic screen. After making certain necessary alterations to the temperatures recorded directly, excellent agreement was found, the maximum difference being only a few degrees for any part of the range between  $1400^{\circ}$  K and  $2700^{\circ}$  K. Similar concordance was found with lamps made at Berlin and at Eindhoven. A typical case is that of the lamp F-117-C, made at Nela Park, which when taking a current of 16 amp was estimated to give a temperature of  $2041^{\circ}$  at the place of origin in September 1924,  $2039^{\circ}$  when tested at the Berlin Osram works in June 1925, and  $2043^{\circ}$  when again returned to Nela Park in

January 1926 The actual discrepancies, small as they are, are believed to be due partly to a lack of constancy of the lamps.

**Absolute Measurement of Voltage**—In connexion with astronomy, electrostatics, hydrodynamics, and mathematics, the properties of the ellipsoid have been studied very assiduously for the last two hundred years Examination questions on them must have been set hundreds of thousands of times It is interesting, therefore, to learn from Prof W M Thornton and W G Thompson's paper to the Institution of Electrical Engineers on Jan 21 that these properties are utilised in their new method of measuring voltages up to 200,000 and of finding the ratio of the electromagnetic to the electrostatic unit of charge At present the most practical method of measuring very high voltages is to find the maximum sparking length at which discharge takes place at this voltage between spherical electrodes Knowing the radii of the electrodes, the temperature, and the atmospheric pressure, the voltage can then be computed or found from tables In the authors' method, a small metallic ellipsoid is suspended by an insulating fibre between vertical circular pole plates When these plates are electrified by the given voltage, its value can be deduced either by a deflexion or an oscillation method The values found for the voltage in this way agree very closely with the values found by sphere-gap methods A drawback to the latter method is that several observations have to be made and a mean taken The accuracy claimed by either

method is 0.3 per cent The authors also made an experiment with the ellipsoid method to measure the ratio of the units, which they give as  $2.9996 \times 10^{10}$ . The mean of the best previous methods is given by Abraham as  $3.0001 \times 10^{10}$  and by Sir Frank Smith as  $2.998 \times 10^{10}$  In making the determination, they assume the values found for the voltages by the spark gap methods

**Temperature of Molecules in a Discharge Tube**—A recent paper by C W W Read (*Proc Roy Soc*, Jan) contains an account of an investigation of the distribution of intensity in some bands ( $\lambda 6100$ — $\lambda 6500$ ) of the molecular spectrum of helium In addition to being an important contribution to the data of band spectra, this is also of interest from the fact that it yields a measure of the temperature of the particular group of molecules involved The intensities were found by the now well-established method of photographic spectrophotometry, with the aid of the new Cambridge form of densitometer, and were shown to conform to theory if the populations of the various energy levels were controlled by a Boltzmann factor, the temperature equivalent of which was  $785^\circ$  abs This is in accord with temperatures of the helium molecules found from the width of the lines in the spectrum, and is, as might be expected, intermediate between the probable temperature of the bulk of the gas in the tube and the electron temperatures which have been found in other discharge tubes by Langmuir's probe method, although it is much nearer to the former

### Astronomical Topics.

**Parallax of Eros**—Dr H Spencer Jones has published a paper on methods of reduction of Eros observations (*Mon Not Roy Ast Soc*, Nov) He notes that to obtain the necessary accuracy the second order terms in differential refraction must be applied, also if there are several images of the planet on a plate, the parallax factors must be computed separately for each image Also, since the mass of the moon is to be found as well as the solar parallax, all plates should be measured both in Right Ascension and Declination He also gives the formulæ for aberration, and asks that these should be applied in the manner stated, for the sake of uniformity He also asks that observers should note which of the secondary stars on the list have been used in their measures, stars that have not been used anywhere need not be observed further, which will save time

**Selenographical Tables and Co-ordinates**—Prof T Banachiewicz, director of the Cracow Observatory, has published these tables and co-ordinates as *Cracow Reprint No 2* He notes that there is now a great increase in the number of occultations of stars by the moon that are observed this is in response to a request from Prof E W Brown, the accuracy of the observations is increased by the distribution of wireless time-signals The present work directs attention to an improvement that can be made in the reduction of the observations, by taking into account the irregularities on the moon's surface Many points on it are above the mean level by a second of arc, others are as much below this level

The tables in this little book give the means of calculating the selenographical co-ordinates of the point on the moon where the occultation takes place Studies of the contours of the moon in different librations have been made, and give some idea of the height of the particular point of the limb

The method of reduction advocated by the author

is according to the Cracovian system, which he introduced some years ago, it is an abridged method of indicating sums of products, analogous to the determinant notation It is explained in the introduction

The tables are based on Brown's lunar tables, Newcomb's formula for the obliquity of the ecliptic, and Hayn's value of the inclination of the moon's equator, which is  $1^\circ 32' 6''$

**A New Canon of Ancient Solar Eclipses**—An important work by R Hiller and P V Neugebauer has been published as an *Erganzungshefte* (Band 8, No 4) to *Astr Nach* (6 gold marks) It is a special canon of eclipses visible in western Asia and in Egypt between 4200 B.C. and 900 B.C. There is an overlap of three centuries with Oppolzer's canon, this was advisable, since improved determinations of the secular accelerations, both in longitude and in other elements, have been made since that canon was published, special acknowledgment is made to the late C Schoch for his useful contributions to the study of the moon's motions There are three separate tables, the most important one gives the elements of 1034 eclipses, also the magnitudes and times of greatest phase at six selected stations Assur (near Nineveh), Babylon, U<sub>1</sub>, Boghaskoi (in Asia Minor), Memphis, and Thebes The second table gives more approximate details of 440 smaller eclipses. The third gives the dates of 350 small eclipses that were not examined in great detail Finally there is a series of maps, one for each period of fifty years, covering the region  $23^\circ$  to  $52^\circ$  east longitude, and  $20^\circ$  to  $45^\circ$  north latitude, these show the central lines of all total and annular eclipses that crossed the region The eclipse of -1062 July 31 is given as total at Ur, magnitude 11.2 digits at Babylon It would seem that a similar canon for China would be useful several eclipse records have come down to us, notably the famous one of Ho and Hi The authors promise a canon of lunar eclipses in the near future

## Progress in Gas and Electric Welding.

THE art of welding iron has been practised for thousands of years, and specimens of ancient welded work, such as chains, are to be found in many museums. Such work was, of necessity, done in the smithy, with a fire, anvil, and hammer. To-day, thanks to the use of gas and electricity, welding can be done wherever it is required, and even bridges, buildings, and ships can be welded instead of riveted. The progress in the art has indeed been remarkable, and only last March the American Society for Testing Materials had a symposium on welding.

In Great Britain the subject is the special study of the Institution of Welding Engineers, at a meeting of which, held at Birmingham on Nov 13, a paper was read on "Boilerworks' Practice", by Messrs E W Thompson and A Jeavons. The flues and furnaces of Lancashire and Cornish boilers were among the first parts to be welded and much work of a similar nature is now done by the aid of water-gas welding machines. An interesting development on the Continent and in the United States is the use of welded drums for water-tube boilers. Such drums cannot, at present, be used in Great Britain owing to the regulations of the insurance companies. The cost of a riveted drum may be £40-£50 a ton, a forged drum £60-£150 a ton according to size, while a welded drum might cost less than £40 a ton. If electric welding is used for pressure vessels a special X-ray radiograph machine is desirable, so that any slag inclusions, gas spots, or incomplete penetration can be detected.

Like so many other industries, that of electric welding traces its history back to Faraday's discoveries, and in the first number of *Electric Welding*, the new house journal of Messrs. The Quasi-Arc Company Limited, is an article on the Faraday Centenary by Mr H M Sayers. Much of the issue, however, is devoted to the use of electric welding

for ships. Descriptions are given of the electrically welded lighter *AC 1320*, built for the Inland Waterways Section of the Royal Engineers in 1918, the *Fullagar*, now the *Shean*, the first completely welded sea-going ship, and two partly welded Japanese vessels. The *Fullagar* was built by Messrs Cammell Laird and Co. in 1920. During her service she has been aground several times, but is still in good condition. She is motor driven and is now engaged in the cement trade in British Columbia.

Another aspect of the subject is presented by the pamphlet "Welding of Structures", by Mr V A Prince, published by the Association of Engineering and Shipbuilding Draughtsmen. Welding, says Mr. Prince, ranks eighth on the list of industries of the United States. As usual, when new processes are applied to production work, it is difficult for the draughtsman to obtain trustworthy data. Mr. Prince's pamphlet contains notes on the methods of electric welding, the plant required, the training of welders, types of welds, and on factors of safety. He then gives designs for a crane girder, a roof truss, and a welded stanchion base. Tests made by the United States Bureau of Standards show that welded stanchion bases are practically as strong as the heaviest types of riveted bases. Welded work will often show a considerable saving in weight and cost over riveted work. The various gas welding methods are water-gas, oxy-acetylene, oxy-coal gas, oxy-hydrogen, and a combined gas and electrical method known as the atomic hydrogen process.

Much research is being carried out in Great Britain, America, Germany, Switzerland, and elsewhere, and methods are becoming standardised and rules formulated. One of the great advantages of using welding for buildings being erected in cities is the absence of noise, such as accompanies riveting.

## Lecture Experiments on the Migration of Ions and the Passivity of Iron.

THE following details of demonstrations successfully made throughout the recent Faraday Exhibition at the Albert Hall may be of use to those who wish to show the migration of ions and the periodic passivity of iron on the lecture table.

## MIGRATION OF IONS

The migration of ions under the influence of an electric current is generally demonstrated by passing a current through an agar-agar gel having in it an electrolyte with a coloured ion, such as copper sulphate, and contained in a glass tube bent into the form of a U. The drawback of this method is that, in order to obtain a good colour, a considerable quantity of electrolyte is necessary, and this increases the conductivity of the gel to such an extent that when more than a small voltage is applied the current produces sufficient heat to melt or in some cases even to boil the gel. Now, as the rate of migration of the ions is proportional to the potential gradient, this small voltage will cause only a slow movement of the coloured boundary, and it is generally found that at least an hour is necessary for any change in position to be observed.

To overcome this difficulty and to make the demonstration more suitable for a lecture experiment, the conditions must be somewhat modified. The electrolyte used is a very small quantity of sodium sulphate, and to render the moving boundary visible an acid alkali indicator, bromo-cresol purple, is also added.

The U-tube is made in the form of a lantern slide, so that the image of the moving boundary can be projected on to a screen. The slide is made by cutting a lantern plate along the dotted lines as shown in Fig 1 and removing the shaded portions. This plate is then cemented between two other plates, using Canada balsam or Coates's cement, thus forming a U-tube in which each limb is  $\frac{1}{2}$  in wide and the limbs are  $\frac{1}{2}$  in apart. The thickness of the U-tube is, of course, the thickness of the glass plate, about  $\frac{1}{20}$  in. It is advantageous to cement another plate to one side of the slide, inserting two narrow strips of glass between this plate and the slide. This provides an air space between the actual slide and the lamp of the lantern, thus reducing the heating effect from this source.

FIG 1

The U-tube is nearly filled with the following solution. Water 100 ml, agar-agar 0.8-1.0 gm., sodium sulphate 0.1 gm. approximately, and sufficient bromo-cresol purple solution to give a good red colour.

When the gel has set, a few drops of very dilute sodium sulphate solution are placed on top of it in each limb and a potential of 200 volts d c is applied across the U-tube, connexion being made by means of platinum wires dipping into the sodium sulphate solution. A purple colour will then move down one limb and a yellow colour down the other, and this movement can be readily observed on the screen, especially if the screen has horizontal lines ruled across it. When the images of the moving boundaries have moved out of the field of view, the current can be reversed so that a yellow colour will move down one limb, obliterating the purple, while the yellow in the other limb will be obliterated by purple.

J. L. BUCHAN

#### PERIODIC PASSIVITY OF IRON

A convenient and effective method for the demonstration of the periodic electrochemical passivity of iron is shown diagrammatically in Fig. 2. *B* is a two-

FIG. 2

volt accumulator, *A* an ammeter reading up to 3 amp, *V* a voltmeter reading up to 3 volts, *R* a variable resistance of 16 ohms, *D* an electro-magnetic relay having two sets of contacts, *a, a'* and *b, b'*, such that one of two circuits is completed according to the position of the moving arm. The coils of the relay take approximately 0.3 amp. *C*, the cell, is a 6-oz. bottle fitted with an ebonite top carrying two brass rods and having two vent holes. A platinum gauze is used for

the cathode and an iron plate ( $1\frac{1}{2}$  in.  $\times$   $\frac{1}{2}$  in.  $\times$   $\frac{1}{8}$  in.) for the anode, these being attached to the brass rods with set screws. 85 ml. of sulphuric acid (35 ml. conc.  $\text{H}_2\text{SO}_4$  to 100 ml. water) are placed in the bottle, the anode is then half immersed. The entire cell is maintained at a temperature of  $45^\circ\text{--}50^\circ\text{C}$ . in a water bath.

Periodicity may be started as follows:

The iron anode is dipped in nitric acid (1/2) and allowed to dissolve freely for 10 seconds. It is then removed from the acid, washed, dried, and attached to its appropriate brass rod. The circuit having been completed, the resistance is adjusted to a point when on immersion of the electrodes in the sulphuric acid the current attains a value of 2.2 amp. This is obtained as soon as the acid has overcome the passive film due to the treatment with nitric acid. Thereupon the electrodes are removed from the warm sulphuric acid and immersed in cold saturated solution of ferrous sulphate rendered decidedly acid with sulphuric acid with the current still running, the passive condition now appears. This state is maintained for 1 or 2 minutes, and finally the electrodes are returned to the warm cell. Periodicity will begin and, under the existing conditions, will be maintained until the anode is dissolved.

An adjusting screw *E* attached to the moving arm of the relay by a spring is provided to overcome the magnetic effect produced by the coils when the anode is in the active condition, that is to say, when the amperage is 2.2 and the voltage 0.7. Further, the contact pillar *P* must be so placed that when the amperage drops to 0.3 and the voltage rises to 1.8 (the passive state) the moving arm does not touch the magnets.

In either of the conditions, passivity or activity, one of the relay circuits is completed, whereby it is possible to light up coloured lamps in an alternating manner.

J. G. N. GASKIN

#### Madras Fisheries \*

IN the Administrative Report of the Madras Fisheries Department for the year ending June 30, 1930, the director, Dr. Sundara Raj, records a general improvement in almost every quarter, especially with regard to research work, in spite of the fact that the fishing season on the west coast was exceptionally bad. The Department has now at its disposal the full-sized steam trawler *Lady Goschen*, which has been remodelled and equipped with a laboratory and a whole-time biologist for research on board, and two well-furnished biological stations on shore at Calicut and Krusadai Island.

The chief aim and immediate work in connexion with the trawler is exploratory, as at present practically nothing is known of the contents and character of the seas outside the ten-mile limit. A survey will be made of the deeper water fishing grounds and the determination of the kinds and quantities of the marketable fish available at different seasons and depths together with investigations into the invertebrates, including plankton. Such research naturally involves the use of the best-known methods of capture, and drift and seine nets were on order with a motor boat for working the Danish seine net. At first the systematic survey will be limited to the

offshore belt to 100 fathoms, up to which the local fishermen with slightly improved boats and nets may be persuaded to extend their operations. The systematic survey of the deep-sea fishing grounds by the *Lady Goschen* began in 1927. During the period between Oct. 31, 1927, and March 10, 1928, she explored the extensive trawling ground within the 100-fathom line which lies to the west, south, and east of Cape Comorin, known as the Cape Comorin Bank. Details of the hauls are given in three appendices to Report No. 3, including the most important fishes and invertebrates, and three charts of the area investigated.

Researches on the Madras oyster show that it flourishes in low salinities and that the freshets in rivers, instead of damaging oyster beds as was formerly supposed, apparently provide the most favourable conditions for spawning and development of the local oyster. A field study of the extensive natural beds at Gokulapalli showed three zones, the first, which is dry for part of the summer except for a few hours during high tide, and on which are only small and yearling oysters and where much spat falls, the second, washed frequently by daily tides and exposed for much less time, where only small oysters grow as their feeding hours are limited, the size increasing with the depth, but where a good deal of spat also falls, lastly, a third zone well below the low-tide level where the oysters are large and the spat scarcely settles at all. It is

\* Madras Fisheries Department Administrative Report for the Year 1929-30 by Dr. B. Sundara Raj, Director of Fisheries. Report No. 1 of 1931. *Madras Fisheries Bulletin*, Vol. 25, 1931. Report on a Systematic Survey of Deep-sea Fishing Grounds by S. T. *Lady Goschen*, 1927-28. Report No. 3 of 1929, *Madras Fisheries Bulletin*, Vol. 23, 1931.

suggested that the spat from the first zone should be collected and transferred to the second zone in spring and finally to the third zone in summer, and that the oysters should be collected and marketed from zone three

Experiments in deep-water tank fishing at Mopad shows that there is an increase in size in the fish. The tank had been stocked with fingerlings of local carp, including catla, which is the quickest growing and attains a large size. Catla are probably bottom dwellers as they are only caught with the Ennur nets and cast nets which descend to the bottom. Investigations into the growth of the catla show

that fish 4-9 in long may grow to 13-17 in in four months and that they attain a length of 13-14 in in a year and 23 in in two years, weighing 6 lb after the first year and 15 lb after two years. Thus it is very suitable for rural pond culture. Several pieces of water have been stocked with these and other fish.

Part of the Report relates to various problems in marine, estuarine, and inland fisheries, including scientific and technical research, administration, pearl and chank fisheries, socio-economic work and publications. Part 2 relates to finance, part 3 to the staff. Appendices deal with statistics.

## The University of Edinburgh

### EXTENSION OF DEPARTMENTS OF GEOLOGY AND ENGINEERING

ON Jan. 28, the Prime Minister opened two recently completed extensions of the University of Edinburgh—the Grant Institute of Geology and the Sanderson Laboratories of Engineering—erected on the West Mains site, on the southern edge of the city, adjacent to the Departments of Chemistry, Zoology, and Animal Genetics, all of which are post-War extensions. The new Institute of Geology has been provided by Sir Alexander Grant, who gave £50,000 for this purpose, the new Engineering Laboratories have been built from a bequest of £50,000 by Mr James Sanderson of Galashiels and a gift of £2000 by the Carnegie Trust. The chancellor of the University, Sir James M. Barrie, presided at each of the opening ceremonies, and his brief introductory remarks were characterised by his usual charm and humour. Among those present at the ceremony in the Geology Department were the Lord Provost of Edinburgh, Sir Thomas Holland, the Right Hon. Sir A. Sinclair (Secretary of State for Scotland), Lord Elgin, Sir Alexander and Lady Grant, and a number of well-known geologists, including Sir John Flett, Profs. W. W. Watts, W. T. Gordon, O. T. Jones, E. B. Bailey, and P. G. H. Boswell.

In opening the building, the Prime Minister spoke in a manner which revealed his own interest in geology and his pleasure in recalling his study of "Vestiges of Creation", and of Hugh Miller's "Footprints of the Creator" and the "Testimony of the Rocks", and of "the wonderful Saturdays spent in trying to discover in the Tynet Burn, where Hugh Miller and others worked, those nodules which split to reveal their secrets. That extraordinarily characteristically Scottish controversy on the six days of creation has contributed more than any other controversy to stimulating the general intellectual curiosity of the generation to which I belong and of the generation immediately preceding. Those who enter these walls now will perhaps not find in the study of geology such an invigorating background."

"I am not at all sure", Mr MacDonald continued, "that scientific investigation can be adequately carried out, can receive the stimulus required for its continued progress, unless those who are experts manage somehow or other to keep in contact with the young men of the street and the market-place. In a conversation I had not long ago with Einstein, I accused him of destroying elementary science. He defended himself with the vigour you can imagine. I laid down the proposition that scientific knowledge must not be so far ahead of common interest that it becomes isolated from the ordinary intellectual life and curiosity of its generation. That is a problem for you to solve. Surely, dull must be the human mind when it ceases to take an interest in the world, its structure, its evolution, the forces that have made

it and that may in time destroy it. When we cease to take an interest in that when we cease to feel the inspiration of that which is on the border-line of the known and the unknown, the knowable and the unknowable, then I think everything that characterises human intelligence will have gone out of it."

Prof. T. J. Jehu expressed the thanks of the University to the Prime Minister and to Sir Alexander Grant.

A similarly distinguished gathering which assembled in the Engineering Department included also representatives of the Sanderson Trustees, Sir Murdoch MacDonald, representing the Institution of Civil Engineers, and Prof. J. D. Cormack, the University of Glasgow. The Prime Minister, in opening the Department, referred to the evolution in the meaning of the term engineering—once purely a military process but now become mainly a civil process—a point which he will carry with him to Geneva. He observed how the University of Edinburgh is equipping itself for the future—a future of skill, of adaptation of the powers of scientific discovery to commercial operations upon the success of which and the international free flow of which depend the well-being and the wealth of every individual nation on the face of the earth. "You are not going to establish", he said, "the greatness of a State or the greatness of a people on material achievements alone. The more we advance in our engineering achievements the more must we be careful of the soul and the spirit of things. Edinburgh turned into a factory only would not be the Edinburgh that inspired us all and made us proud that it is our capital city. Nor must the city be a dead museum. The ghosts of the past must never be banished from the streets of Edinburgh. But while preserving that, while planning our Edinburgh that these ghosts are not laid by the efficient brutalities of up-to-date materialism, we must see that our Edinburgh in its institutions, in its work, above all in its University, must equip its young men and its young women with a full knowledge of the past and yet able and efficient to make future contributions to the glory and greatness of our city. Brains, knowledge, and capacity are to be put at the disposal of what I am convinced is a developing nation. In these days the development of a nation and its prosperity depend very largely on the way that it uses mechanical power. The adaptation of driving power to new forms of material, the capacity to apply scientific discovery, are the lines upon which this nation is going to move out of the past into the future. All things pass away, everything becomes new, and that text cannot be better applied to anything than to the evolution of power to transport."

Sir Thomas Hudson Beare offered to the Prime Minister and to the Sanderson Trustees the thanks of the University.

### Senility in Plants.

IT is a very old subject of controversy whether a vegetatively propagated 'clone' can be maintained in cultivation indefinitely or whether, in the course of time, quite apart from the incidence of disease, the individuals of the clone would 'degenerate' because of their increasing age. It is true that time after time a new piece is separated, by some recognised horticultural method, and started into growth anew in some fresh location, but it is argued that such a new start does not compare with the new start made by the plant which emerges from the seed.

Any comparison is difficult, of course, because the seed results from fertilisation, and in this case the new individual is inevitably a new beginning, a fresh combination genetically, but it is still not clear that this new piece, which forms a fresh link in the series in the vegetatively propagated clone, is not just as vigorous and fresh in its growth as any average seedling of the same stock, and certainly there is still wanting definite evidence that such new individuals ultimately prove 'senile' because of the long period of time since this vegetatively propagated material emerged from a fertilised egg.

'Degeneracy' in the potato has now been traced in many cases to the cumulative effects of a transmissible virus disease, handed on with the new piece, in the process of vegetative propagation, so that its effect in successive vegetatively propagated generations begins to be exerted earlier and with more disastrous results. In many such cases, now that the etiology of the virus is better understood, it has been possible to isolate from amongst such degenerate strains healthy plants, free from virus, which seem as vigorous and productive as ever.

Nevertheless, the doctrine of senility still has advocates. A very clear and valuable summary of the literature in this controversial field is given by A. P. C. Bijnhouwer, with a comprehensive bibliography, in the *Journal of Pomology and Horticultural Science*, vol. 9, June 1931, one noticeable omission, however, is the lack of reference to the work of Dr. A. B. Stout, of the New York Botanic Garden.

### University and Educational Intelligence.

CAMBRIDGE.—Dr. C. E. Wynn-Williams, of Trinity College, has been elected to a moiety of the Clerk Maxwell scholarship vacated by W. H. Watson.

Sir F. Gowland Hopkins has been granted leave of absence for such one term as the General Board may approve in each academical year in which he holds the office of president of the Royal Society.

NOTICE is given by the Royal Society that applications for the Government Grant for Scientific Investigations must be made upon forms, obtainable from the Clerk to the Government Grant Committee, Royal Society, Burlington House, London, W. 1, and returned by, at latest, March 31.

THE eighth annual Report of the Ella Sachs Platz Foundation for the advancement of scientific investigation has recently been published. During 1931 twenty-six grants were made, nineteen of which were outside the United States. At present, researches in scientific subjects with a bearing on problems in medicine and surgery are favoured. Applications for grants for 1932 should be sent to Dr. Joseph C. Aub, Collis P. Huntington Memorial Hospital, 695 Huntington Avenue, Boston, Mass., before May 1.

AN American International Fellowship, value 1½ dollars, is being offered to women graduates by the American Association of University Women, and Spanish International Fellowship, value 4000 peset by the Cultural Relations Committee of the Spanish Ministry of Foreign Affairs. Information with reference to the fellowships and application forms obtainable from the British Federation of University Women, Crosby Hall, Cheyne Walk, S.W. 3. Completed forms must be returned by Feb. 14.

THE University of Leeds report on the year 1930-records substantial additions to its resources and increase in the number of its students. A bequest of £100,000 by Lord Brotherton, who died during the year, brought the total amount of his benefaction to the University up to about a quarter of a million sterling. A new residential hall for students open at the beginning of the year was continuously occupied to its utmost capacity and proved an unqualified success. A new building providing ample accommodation for the teaching of physics under ideal conditions was nearly completed, and good progress was made with an extensive block of buildings for the chemistry department and with a pathological institute. Other notable happenings of the year were the introduction of a system of grading of salaries and sea increases of salaries for the members of the academic staff, the celebration of the hundredth anniversary of the commencement of the medical school and the recognition of courses at University College, Hull, leading to success in the first M.B. examination of the University of London, as qualification for exemption from the first M.B. examination at Leeds.

'General science' courses and the teaching of biology in schools are discussed from various points of view in the January number of the *New Era* by Prof. Winifred Cullis, who contributes a general introduction to the other articles by Prof. Julian Huxley, whose subject is "Biology: a Cultural Subject" and half a dozen other writers. Mr. S. A. McDowall, chaplain and senior science master at Winchester College, describes the aims and content of his five years continuous course in general science for boys from 13 to 18 years of age, beginning with physics, geography and proceeding, through hydrostatics, heat, chemistry, sound and light, electricity and magnetism, and molecular physics, to biology in the fifth year, linked with the principles and history of science. He describes also how the course was gradually evolved from a discontinuous and imperfectly correlated course in which no biology was included. Miss Drummond, headmistress of the North London Collegiate School and president of the Association of Women Science Teachers, deals with some of the practical problems arising in connexion with teaching biology in girls' secondary schools. Miss von Wyses concludes a paper on "Nature Study as an Approach to Biology" with an outline of a scheme of work. Mr. S. R. Slavson, sometime director of science and industrial arts education in the Walden School, New York, contributes a paper on "Integrated Science for Young Children", in which he declares his conviction, based on ten years' experience of science teaching with children from four to sixteen years of age, that the unified science programme is superior to specialities as a means of developing scientific attitudes, arousing interest, and vitalising knowledge. There are also papers on science in South African high schools, 'rural science' in a village elementary school, and broadcast science for schools, all pointing in the same direction.

## Calendar of Geographical Exploration.

Feb 11, 1864 — Central Arabia

A Levantine Italian, Carlo Guarmani, reached Teima on a mission to buy stallions for the French. From Teima onwards Guarmani passed as a Turk. He ranged the steppe south of Teima, and was the first European to reach the ancient and famous oasis of Kheibar, with its negro population. He was sent as a prisoner to Aneiza, but from that point onwards met with no difficulties. He crossed to Jabal Shammar, where the Emir was anxious to do business with him. He went in and out of Hail, to Teima and back, visited nearly all the oases of the Jabal, and finally crossed the Nafud. Guarmani took a compass with him, and took so many bearings that he may be considered to be the pioneer of scientific cartography in central Arabia. His many cross journeys gave him opportunity to record the orography of the country, and he noted the great westward and south-westward extent of the oases and wells on which the Shammar depend. Guarmani had prepared himself for the journey by a long study of the Arab tribes, and in 1851 he had conducted an expedition to Jauf.

Feb 12, 1541 — Exploration and Conquest of Chile

Pedro de Valdivia founded the town of Santiago, whence he proceeded to establish fortified settlements north and south of that centre, and east of the Andes. The country was opened up as far south as Valdivia, founded in 1552, and beyond it to 40° S. An expedition was sent by sea to Magellan Strait, and a land expedition to that region was planned, but not carried out owing to the death of Valdivia. East of the Andes, Valdivia may have reached the Negro or the Colorado River. The province of Cuyo which he conquered is now included in the Argentine.

Feb 13, 1500 — Cumana and the Island of Margarita

Alonso Niño of Moguer, who had accompanied Columbus as a pilot, left Cumana for Spain. During his voyage, Niño had sailed to the Gulf of Paria, and his men were the first Spaniards to land on the island of Margarita, the centre of the pearl fishery. The party then proceeded to Cumana and explored the mainland to the west; gold and pearls in some quantity were obtained on this voyage and thus helped to attract other vessels to the region.

Feb 13, 1858 — Sources of the Nile

R. F. Burton and J. H. Speke reached Lake Tanganyika. They had set out to ascertain the limits of the Sea of Ujiji (Tanganyika) and to study the economic and ethnographic conditions of the region round it. They also hoped to reach 'the reputed' Lake Nyasa. They were obliged to give up the latter quest, but Speke on the return journey left Burton for a northward expedition, during which he discovered Lake Victoria Nyanza, which he was convinced was the source of the Nile. In 1860, Speke and J. A. Grant set out from Zanzibar and reached the outlet of the lake, where the Ripon Falls, the birthplace of the Nile, were discovered, on July 28, 1862. Speke also discovered the Kagera River, now known to be the most remote headstream of the Nile, though he was uncertain of this fact. Stanley, in 1875, circumnavigated Victoria Nyanza, confirming Speke's statement that it was one large lake and not five small ones as Schweinfurth had thought. He also explored part of the Kagera.

## Societies and Academies.

LONDON.

Royal Society, Jan 28 — T. M. Lowry and H. K. Gore. Optical rotatory power of vapours. The optical rotations of the vapours of camphor and of camphor quinone are  $(M)_{5893} = 83^\circ$  at  $180^\circ \text{C}$ , and  $-146^\circ$  at  $200^\circ$ , respectively. The curve of rotatory dispersion of camphor vapour shows a sharp maximum  $(\alpha)_{180^\circ} = 2000^\circ$  at  $3200 \text{ \AA}$ , followed by a reversal of sign at  $3020 \text{ \AA}$ , and a negative maximum  $(\alpha)_{180^\circ} = -1860^\circ$  at  $2800 \text{ \AA}$ . A 'step-out' on the short wavelength side of the positive maximum is in harmony with the fact that the curve of circular dichroism of a solution of camphor in hexane extends over only a part of the absorption band, on the side of longer wave-lengths. A solution of camphor in cyclohexane shows a positive maximum  $(\alpha)_{200^\circ} = 2600^\circ$  at  $3200 \text{ \AA}$ , followed by a step-out, a reversal of sign, and a negative maximum  $(\alpha)_{200^\circ} = 2100^\circ$  at about  $2720 \text{ \AA}$ . The curve of rotatory dispersion of camphor quinone passes through a negative maximum  $(\alpha)_{200^\circ} = -500^\circ$  at  $4950 \text{ \AA}$  for the vapour and  $(\alpha)_{200^\circ} = -450^\circ$  at  $4940 \text{ \AA}$  in cyclohexane, followed by a reversal of sign at  $4740 \text{ \AA}$  and a positive maximum  $(\alpha) = +300^\circ$  at  $4440 \text{ \AA}$ . — H. W. B. Skinner. The excitation potentials of light metals. (1) Lithium. There are critical potentials and also, apparently, some bands of radiation in the voltage region less than 20 volts. These must be associated with the conduction electron system. But the more important aspect of the work is concerned with the emission of the  $K$ -radiation of lithium metal. The radiation was found to consist of a band with a maximum frequency corresponding to 54 volts. It is shown that the ionisation of the  $K$ -shell alters the levels in the metal in such a way that there are empty levels around the ionised atom into which the  $K$ -electron can switch. — E. G. Cox. The crystalline structure of benzene. By consideration of the intensities of the X-ray reflections from a number of lattice-planes it has been found possible to decide on the arrangement of the molecules in the lattice, and in addition it is found that the experimental results are strongly in favour of a flat-ring molecule.

LEEDS.

Philosophical and Literary Society, Dec 8 — J. Blakey. The Schur quadrics of the trimodal cubic surface. — R. Whiddington and J. E. Taylor. Preliminary note on the photographic action of electrons. The law of blackening of a photographic film by electrons of speed within the region 50-300 volts has been studied quantitatively. The law is similar to that in the case of light. The photographic effect for a given number of electrons falling on the film is independent of their energy within the region examined. — J. Ewles. The measurement of ionisation currents by means of an alternating current bridge and valve amplifier. The ionisation chamber is used as a capacity in one arm of an alternating current capacity bridge. The balance is detected by a multistage thermionic valve amplifier in conjunction with an output transformer and alternating current detector. After a balance has been obtained and the ionisation current then allowed to disturb it, it is possible to restore the balance by a series resistance in an arm adjacent to that of the chamber, when the value of this series resistance is proportional to the ionisation. Since a compact multistage amplifier may be used, the method is capable of very great sensitivity. — G. W. Brindley. On the intensity of reflection of X-rays by perfect crystals. The observed intensities of reflection of X-rays from highly perfect diamond crystals agree

with Ewald's theory only for angles of reflection less than  $45^\circ$ , at greater angles there is a large divergence between the observed intensities and the theoretical predictions. Ewald's theory does not take into account the atomic structure factor. When this factor (corrected slightly for zero point energy in the diamond lattice) is taken into account in the manner suggested by the work of Darwin, the theoretical predictions are then of the same general form as the experimental results both at large and small angles of reflection.—F W Spiers. The diffusion of mercury drops on rolled tin-foils. Elliptical areas of amalgam (11.8 atomic per cent mercury) are formed, the crystal structure of which is found to be hexagonal.—H. M. Dawson and G V Hall. Comparison of the catalytic effects produced by acids in aqueous and in aqueous alcoholic solutions. Observations on the acetone iodine reaction show that the catalytic effects produced by buffer mixtures of the constant acid, variable salt type, are precisely the same for aqueous and aqueous alcoholic solutions.—H. M. Dawson and A. Key. Determination of ionisation constants of acids in aqueous alcoholic solutions on the basis of catalytic effects. The catalytic effect of chloroacetic acid on the acetone iodine reaction in 75 per cent alcohol has been used to determine the ionisation constant of the acid and also the catalytic activity of the chloroacetic acid molecule. The observed dependence of the reaction velocity on the concentration of the acid indicates that the ionisation of the acid conforms closely to the requirements of the mass law.—F J. Garrick. Note on the use of acidimetric indicators in argentometry. Quite accurate results may be obtained in silver titrations by the use of bromphenol blue, methyl orange, or methyl red as adsorption indicators. The method possesses no advantage in respect of accuracy over those usually employed, but is particularly convenient in the special case where both an acidimetric and an argentometric titration of the same solution are required.—E T Everingham and W H Pearsall. The effects of tartaric acid and of glucose on the metabolism of vine leaves. Both tartaric acid and glucose reduce the rate of hydrolysis of protein in vine leaves. Tartaric acid appears to reduce the rate of deamination of amino-acids, and apparently tends also to reduce the rate of carbohydrate loss. These effects are more marked in young leaves or in leaves illuminated by weak light. When glucose is supplied, there is a tendency towards protein synthesis.

## PARIS

Academy of Sciences, Dec 28.—Maurice Hamy. A property of the equation obtained on equating to zero the distance of two planets,  $P, P_1$ , which do not meet at real points.—Marcel Brillouin. The development in harmonic functions on the sphere of a function the value of which is given at each point of the continental seashore. Conformal representation.—H. Deslandres. Simple relations between the molecular spectrum and the structure of the molecule.—L. Cayeux. The secondary origin of the radiating structure of old marine oolites. Arguments are given in favour of the view that the radial structure of oolites is a secondary acquirement, and is independent of the concentric structure.—Charles Nicolle, Charles Anderson, and Jean Laigret. Study of the spirochaetes of the first three cases of recurrent Spanish-African fevers met with in Tunis.—T. Levi-Civita. Surfaces admitting a triangular network of parallel lines.—J. Drach. Remarks on the preceding communication.—E. Mathias. Lightning formed of a series of luminous lines.—Lucien Daniel. Natural layering of the aerial rhizomes of *Tanacetum Balsamita* grafted

on *Chrysanthemum frutescens*.—N. Aronszajn. The decompositions of uniform functions.—B. de Kerekjárt. The existence of square roots in continued groups.—B. N. Prasad. The summability of a conjugated series of a Fourier's series.—C. Visser. The angular derivative.—J. Le Roux. The rôle of the group of relativity in classical mechanics.—J. Haag. The gravity pendulum.—D. Barbier. The probable eccentricities of the visual double stars the orbits of which are still unknown.—Emile Sevin. Concerning binary systems.—F. Holweck. A new model of the Holweck-Leja pendulum. The value of gravity at points in continental France and in Corsica.—Henri Abraham. The maintenance of a room at constant temperature. The room was electrically heated and the temperature controlled by a toluene thermostat. Artificial ventilation was found to be necessary. With the precaution described, the average daily temperature was kept constant within  $0.001^\circ \text{C}$ .—Henri Chaumat and Edouard Lefrand. Electrostatic machines.—Duffieu and G. Trolet. The luminous phenomena produced by the rolling of amalgams on glass in a vacuum. The experiments with mercury described in a previous note have been repeated with mercury containing known amounts of impurities (zinc, cadmium, sodium).—R. de Malleman and P. Gabiano. The magnetic rotatory power of argon. The Verdet constant of argon at  $0^\circ \text{C}$  and 760 mm pressure is  $9.2 \times 10^{-6}$ . The magnetic rotatory power of argon is higher than that of nitrogen, oxygen, or hydrogen.—J. Cabanne and Mlle Osborne. Theoretical considerations on the anomalous depolarisation of the Raman lines in uniaxial crystals.—Mme Irène Curie. The nuclear  $\gamma$ -radiation excited in beryllium and in lithium by the  $\alpha$ -rays of polonium.—F. Joliot. The excitation of the nuclear  $\gamma$ -rays of boron by  $\alpha$ -particles. The quantum energy of the  $\gamma$ -radiation of polonium.—P. Lecomte du Nouy. The measurement of the hydrogen ion concentration of liquids by means of a rotatory electrode. With the form of electrode described, equilibrium is attained in less than one minute and the quantity of liquid required is 1 c.c. or less.—A. Girard and G. Chaudron. Contribution to the study of ferromagnetic ferric oxide. Four specimens of ferromagnetic ferric oxide were studied, one natural lepidocrocite and the others prepared by laboratory methods. Curves showing the changes produced in the magnetisation by rise of temperature are given.—Hikoichi Shiba and Tokunosuké Watanabé. The structures of crystals of northupite, bromonorthupite, and tychite.—Mlle. Foret. Calcium chromo-, selenio-, and sulphoaluminates.—E. Carrière and Juillard. Evolution of the system iodine, excess of soda.—R. Paul. Some derivatives of the tetrahydrofuryl series.—Marcel Godchot and Pierre Viéles. The dilactic acids.—Léon Enderlin. Researches on the chemistry of the rubrenes. The chemical properties of rubrene and its homologue dimethylrubrene were compared and found to be closely parallel.—R. Delaby, R. Charonnat, and M. Janot. The radioactivity of the waters from some summits of the Vosges. The waters examined were collected at heights between 700 metres and 1315 metres above sea-level. It was found that the radioactivity of the granites and that of the waters flowing from them varied in the same sense.—P. Idrac. A submarine temperature recorder. An electrical recording thermometer modified to meet the special conditions, and capable of an accuracy of  $0.01^\circ \text{C}$ . A typical record is reproduced.—Frank A. Perret. The new dome of Mt Pelée.—R. Lamé. The geographical distribution of some marine algae in the northern region of the coasts of Portugal.—P. Choux. *Stapelopsis Madagascariensis*, a cactus-shaped *Ceropegium* of Madagascar.—E. Bigeard. The *Pedrastrum*

of France — Pierre Lesage Contributions to the study of the exchange of seeds of the same species of plant between two different stations

(To be continued)

#### ROME

Royal National Academy of the Lincei Communications received during the vacation — G Armellini A new cosmogonic interpretation of the equipartition of energy among the stars If the cosmogonic hypothesis of Sir Norman Lockyer and R Du Ligondès—according to which nebulae and stars were originally formed by the union of large numbers of pre-existing meteorites—is accepted, the equipartition of energy among the stars follows as a mathematical consequence This result throws doubt on the conclusion of Jeans, who, by comparing the movements of the stars with those of gas molecules, calculated that impacts of stars over a period of at least five to ten million million years would be necessary to effect equipartition of their energies — F Zambonini and Silvia Restaino Double sulphates of rare earth and alkali metals (14) Sulphates of praseodymium and sodium Study of the isotherm of the system  $\text{Pr}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  for  $25^\circ$  shows the existence of two crystalline compounds of the formulae  $4\text{Pr}_2(\text{SO}_4)_3 \cdot 5\text{Na}_2\text{SO}_4 \cdot 8\text{H}_2\text{O}$  and  $\text{Pr}_2(\text{SO}_4)_3 \cdot \text{Na}_2\text{SO}_4 \cdot 2\text{H}_2\text{O}$  — L Cambi and A Cagnasso Manganic dithiocarbamates Manganic *N*-piperidyl-, *N*-*N*-isodibutyl-, and *N*-*N*-dibenzyl-dithiocarbamates are described — G Rovereto Folds with inclusions (*a truciolo*) and two-way folds — G Barba Generalised parallelism in a  $V_3$ -C Miranda Asymptotic properties of Newtonian potentials due to illimited distribution of masses — P Clemente Majoration of the periodic solutions of an ordinary linear differential equation of the second order — A Rosenblatt The stability of the laminar movements of incompressible viscous liquids — A Masotti The centre of hydrostatic pressures — G Occhialini A magnetic spectrograph for  $\beta$ -rays emitted by feebly radioactive substances A description is given of a simple magnetic spectrograph which allows of the use of a wide irradiating surface and is especially useful for the examination of feebly radioactive substances like rubidium and potassium — C Dei A dynamic arrangement for comparing the constants of two triodes — Zvi Jolles Study of the oxidising properties of normal diazo-hydrates Various reactions indicate that the oxidising properties of diazo-hydrates are very general in character — F De Carli Viscosity of mixtures of stannic chloride with aromatic hydrocarbons The viscosity isotherms of mixtures of stannic chloride and toluene show that, unlike benzene, toluene is able to associate appreciably with stannic chloride at temperatures between  $20^\circ$  and  $30^\circ$ , but the data obtained are insufficient to prove the existence of a definite compound between the two substances — E Parisi The presence of a new sugar in dextro-rotatory honeys Conifer honeys contain, in addition to the sugars of other honeys, a glucobiose which has a molecular weight, determined cryoscopically, varying from 280 to 340 according to its degree of purity, and a specific rotatory power of  $+90^\circ$  to  $+110^\circ$  The sugar may occur ready-formed in the tree or may result from an enzymic action similar to that which gives rise to Croft Hill's revertose — G B Cacciamali Orogenic conflicts — A Debenedetti A method of measuring the maximum birefringence of biaxial minerals with the help of the Federow plate The method described allows of the determination of the maximum birefringence of a mineral from the two refractions corresponding with two positions of a section maintained normal to a principal plane of optical symmetry — G Tallarico The volume of

the caryopses of grain in relation to their nutritive value The results of experiments with turkeys show that small-corned grain has a greater nutritive and biological value, at any rate during the development and growth of the birds, than grain with large corns — M Curzi A new species of *Helminthosporium* in a disease of the banana encountered in Italian Somaliland This disease, manifested by spots on the stems, leaves, etc., is due to the organism *Helminthosporium gibberosporum* n. sp. — Giulio Cotronei and Aldo Spirito Zoological constitution and grafting New experiments between Anura and urodeles — Aldo Spirito Grafting from the triton to the edible frog (2)

### Forthcoming Events.

#### Societies

#### FRIDAY, FEBRUARY 5

- ROYAL SOCIETY OF MEDICINE (Laryngology Section), at 5 — Discussion on Common Colds and their Sequelae  
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 — Prof A R Hobbs Puerperal Sepsis, with an Account of the Treatment of Puerperal Infection by Glycerine Drainage (Hunterian Lecture)  
GEOLOGISTS' ASSOCIATION (in Botany Theatre, University College) (Annual General Meeting), at 7 30 — Prof W W Watts Fossil Landscapes (Presidential Address), and presentation of Foulerton Awards to F Gossling and Dr S W Wooldridge  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9 — Dr G C Simpson Weather Forecasting

#### MONDAY, FEBRUARY 8

- ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 — Prof J A Ryle The Natural History of Duodenal Ulcer (Hunterian Lecture)  
ROYAL GEOGRAPHICAL SOCIETY, at 8 30 — H Clutterbuck The Oxford Expedition to Akpatok Island

#### TUESDAY, FEBRUARY 9

- ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 — Dr G Shearer Research Work on Crystal Analysis (1)  
INSTITUTION OF ELECTRICAL ENGINEERS (North-Western Centre) (at College of Technology, Manchester), at 7 30 — Prof J K Catterson-Smith Everyday Uses of Electricity (Faraday Lecture)  
QUEKETT MICROSCOPICAL CLUB (at 11 Chandos Street, W 1), at 7 30 — Annual General Meeting  
PHARMACEUTICAL SOCIETY OF GREAT BRITAIN, at 8 30 — Dr H E Archer Biochemistry, Chemical Pathology, and Pharmacy (Address)

#### WEDNESDAY, FEBRUARY 10

- ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5 — Prof H A Harris The Comparative Anatomical Aspect of Pre-Natal, Infantile, and Adult Disease in Man and Animals, with special reference to Bone Growth (1) (Hunterian Lecture)  
ROYAL SOCIETY OF ARTS, at 8 — J A R Stevenson The Craft of the Decorative Iron Worker (Lecture)

#### THURSDAY, FEBRUARY 11

- ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15 — Prof H G Cannon Feeding and Digestion in Invertebrates (4)  
INSTITUTION OF MECHANICAL ENGINEERS (at Leeds), at 7 30 — Lt B Atkinson The Mechanical Aspects of Electricity (Thomas Hawksley Lecture)  
INSTITUTION OF WELDING ENGINEERS (at Institution of Mechanical Engineers) — Declaration of name of prize winner, Award of Prize and Gold Medal, Paper by or on behalf of prize winner Welding and Cutting on Railways and Tramways

#### FRIDAY, FEBRUARY 12

- ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Committee) (at 52 Upper Bedford Place), at 4 —

- Mrs. Seligman The Method of Exhibiting Genealogical Data—C W. M. Hart Is it correct to regard all Australian Tribes as on the same Economic Level?  
 ROYAL ASTRONOMICAL SOCIETY, at 5—Anniversary Meeting  
 ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—Prof H A HARRIS The Comparative Anatomical Aspect of Pre-Natal, Infantile, and Adult Disease in Man and Animals, with special reference to Bone Growth (2) (Hunterian Lecture)  
 ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Sir John Cadman Petroleum A Record of Achievement in Applied Science

## Public Lectures.

## FRIDAY, FEBRUARY 5

- UNIVERSITY COLLEGE, at 5 30—H N Gresley High Pressure Locomotives—Prof H A R Gibb The Climax of Arab Culture

## SATURDAY, FEBRUARY 6

- HORNIMAN MUSEUM (Forest Hill), at 3 30—Prof J. R. Answorth-Davis Shell-Fish in relation to Man

## MONDAY, FEBRUARY 8

- GUY'S HOSPITAL (in Physiological Theatre), at 5—Prof H A HARRIS The Use of X-Rays in Physiological Investigations (2)  
 ST BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE, at 5 30—Dr L Findlay The Feeding and Nutritional Disease of the Infant (1)  
 KING'S COLLEGE, LONDON, at 8—C J Gadd Babylonian Myth and Ritual

## TUESDAY, FEBRUARY 9

- UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 15—Prof A E Boycott Hypertrophy and Atrophy (1) (Succeeding Lecture on Feb 16)

## WEDNESDAY, FEBRUARY 10

- ROYAL INSTITUTE OF PUBLIC HEALTH, at 4—Dr M. B. Ray The Prevention and Treatment of Industrial Rheumatism  
 SCHOOL OF ORIENTAL STUDIES (jointly with Royal Anthropological Institute), at 5—Dr R S Rattray Hausa Poetry  
 UNIVERSITY COLLEGE, at 5 30—Dr. R S Hutton The Field of Industrial Librarianship  
 BELFAST MUSEUM AND ART GALLERY, at 8—O Davies The Great Days of Egypt

## THURSDAY, FEBRUARY 11

- ST BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE, at 5 30—Dr L Findlay The Feeding and Nutritional Disease of the Infant (2)  
 KING'S COLLEGE, LONDON (at 16 Russell Square, WC 1), at 6—S P Turn Economic Conditions in Russia To-day Accumulation of Capital and Savings under the Five-Year Plan

## FRIDAY, FEBRUARY 12

- ST BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE, at 5 30—Dr L Findlay The Feeding and Nutritional Disease of the Infant (3)  
 UNIVERSITY COLLEGE, at 5 30—Prof Sir Reginald Fleming Johnston China in the Ancient World

## SATURDAY, FEBRUARY 13

- HORNIMAN MUSEUM (Forest Hill), at 3 30—Mrs Olwen Brogan Town-Life in the Roman Empire

## Conferences.

## SATURDAY, FEBRUARY 6.

- SCHOOL NATURE STUDY UNION (in Botanical Theatre, University College), at 3—Sir Arthur W Hill The Andes of Bolivia, with some Account of the Archaeology and Botany of the Region

No. 3249, VOL 129]

## TUESDAY, FEBRUARY 9

CONFERENCE ON MECHANISATION AND BRITISH AGRICULTURE (at Rothamsted Experimental Station, Harpenden), at 11 30 A M

- J E Newman Engineering Developments and Possibilities  
 Prof J A S Watson Combination of Livestock with Systems of Mechanised Farming  
 Sir John Russell The Maintenance of Soil Fertility under Mechanised Farming Systems

## International Co-operation

THE unanimity with which some form of deliberate planning of our national resources and of our industrial if not of our social and economic life has been suggested in technical journals of high standing and ranging over chemical industry, engineering, and the electrical and gas industries is highly significant, and is evidence of the growing realisation that a scientific age can only be safe if the powers of science are exercised with wisdom. In a speech at the annual dinner of the British Association of Chemists, Dr E. F. Armstrong, after referring to the lack of scientific knowledge on the part of many of the world's political leaders, their opportunism and lack of definite plans, urged that chemists with other scientific workers should use their influence in industry and professionally in support of leaders who would attempt to plan the international reconstruction of the world on the basis of a definite five-year or similar plan.

It is not industry alone, however, which is insisting that problems of to-day require solution on world lines by scientific method. Even in the political sphere, the only real pieces of successful reconstruction work in post-War Europe have been schemes based on an impartial scientific analysis of the problem by the relevant experts and linked up with the appropriate action. The Austrian and Hungarian reconstruction schemes and the Greek Refugee Settlement scheme are examples of a new technique in international questions, and demonstrate beyond question the function of the technical expert in linking up knowledge and power.

The recently published report of the Basle Committee of Experts demonstrates how imperative is the need for concerted action if financial paralysis of the world is to be avoided. The dislocation at present taking place may well involve a profound change in the economic relations of one nation with another. Referring to this essential need for international co-operation, in an address on world unemployment to the Institute of International Relations at Geneva, Prof P. H. Douglas, of the University of Chicago, pointed out that it is doubtful whether the fierce national jealousies of the world would permit the required pooling of resources and common policy, and that the issue depends upon intelligence as well as upon goodwill. There is much in the preliminary negotiations regarding the Lausanne Conference which indicates that such doubts are well founded and political prejudices still unwilling to recognise facts.

In another field we find that Major Lefebure's plea for a scientific study of the disarmament problem, and in particular for the creation of a representative scientific organisation under the League of Nations to advise on actual means for giving effect to international policy as to research on armament type, has been passed over in making preparations for the present Disarmament Conference. Further, the results of the impartial scientific investigations of many of the vexed and difficult problems related to the South Manchuria railway which have been carried out during recent years by the Institute of Pacific Relations have been brushed aside by politicians. The lack of courage, foresight, and understanding displayed in the handling of the Manchurian dispute can only be rightly assessed when we consider how much has already been provided by scientific investigations as a basis for an impartial settlement.

These recent events demonstrate that the gap between knowledge and power to which Prof Zimmern directed attention some years ago in his brilliant study, "Learning and Leadership", has become a dangerously critical problem. Leadership has definitely weakened under the pressure of public opinion, and more and more the only hope of solving vexed problems is in entrusting the handling of them to impartial experts who are not dependent upon public opinion. The Dawes and Young Commissions were not only valuable because of the great work they did, but even more because they are typical of a new method of dealing with such questions. They applied the forces of science and expert skill and wisdom to a problem declared insoluble by governments and hopelessly vitiated by human prejudice. That their solution was only temporary and that the problem threatens to be sucked once more into the maelstrom of politics merely indicates the imperative need for extending this same technique to other international problems which react on these issues.

"Statesmen are not enough to solve the problems which arise in international affairs", General Smuts has said in a lecture on "Democracy". "The nations must become accustomed to look to the organised system of the expert report, which gives a just and impartial lead to governments and public opinion and should be regularly accepted just as judicial decisions are accepted as a matter of course."

Not only the discoveries of science, but the mature, sober, impartial spirit of science is what is above all else necessary for the functioning of the new international system. The application of the true scientific spirit to human affairs, if it were humanly possible, would mean such a reign of justice and fair play on earth as only poets have

dreamt of. The cool, serious, gentle spirit of science, above all, wanted in the storm-tossed domain of international affairs. The scientific expert must prove a most valuable link in the international organisation of the future. He will function normally and dispassionately, whether international storms may rage outside, and his findings will be quietly accepted in the end, as the higher wisdom and the better way."

In the last two years a beginning has at any rate been made on some of the problems which arise out of the application of scientific method to international affairs. At a Conference of Institutions for the Scientific Study of International Relations held in Copenhagen in June 1931, progress was made in the fundamental study of international relations, and the possibility of a systematic study of actual problems on international relations, either on the lines of the Institute of Pacific Relations, or by entrusting particular researches to individual institutions, was discussed. A study of the international implications in the relations between government authority and private economic activities of individuals and groups, with special reference to the new forms of public management, control, and supervision, national or international, direct or indirect, which have grown up since the War, and the motives and policies underlying them is contemplated at the next Conference. The possibility of a fundamental scientific study of the problem of disarmament was also suggested.

In industry, where an international outlook has become much more prevalent and the importance of scientific leadership is increasingly recognised, the possibilities visualised by General Smuts have found even more concrete expression. Sir Harry McGowan has already thrown out the suggestion of an International Council for Chemical Industry which would plan chemical industry as a world unit in regard to production, research, and development. The World Social Economic Conference held at Amsterdam last August led to definite proposals for a five-year world plan which was to be based on world solidarity, the modification of national economic policy in accordance with its effect on world economy, and the pooling of losses due to the War. The plan involves a general moratorium on all war debts and reparation payments, a series of international loans and agreements in regard to markets and production, and the establishment of a World Research Council or Planning Board to stimulate thought and action in the planning and rational organisation of the social and economic life of the world.

Were not scientific workers, as Ruskin remarked

"still eager to add to our knowledge, rather than to use it", the new opportunities confronting them of making a vital contribution to the solution of our present difficulties would have been seized with avidity. Not only industry but also whole sections of the nation are disposed to accept the leadership of science and to adopt a well-thought-out and comprehensive scheme of national and international reconstruction based upon an authoritative and scientific analysis of the whole situation. No such scheme can, however, be produced until scientific workers are sufficiently concerned with the economic and social consequences of their work to co-operate with industrialists and others who are imbued with the scientific outlook and capable of assessing the value of scientific method and knowledge. In such co-operation there should be adequate safeguard against the neglect or abuse of human values, which Bertrand Russell fears and depicts so vividly in his sketch of scientific society and scientific government.

There are all the signs that the age of individualism and competition is passing and will be succeeded by an age of co-operation and planning on a world scale. The danger is still acute that old prejudices may delay the transition and precipitate a conflict from which the recovery of civilisation will be impossible. The existence of political prejudices in government circles should not lead us to overlook the facts that nowhere does prejudice and individualism linger more persistently than among the very scientific workers whose discoveries have made world co-operation and the renunciation of war at once inevitable and urgent. Even the difficulties and limitations on the intellectual classes and the intellectual progress of mankind directly imposed by the burden of armaments under present conditions have not sufficed to rouse general interest among scientific workers, or to induce them to make their fitting contribution in the analysis of the problem. Statesmen, indeed, need to take account of our prejudices as well as of the facts of life. Reason alone may be an incomplete guide for the control of human affairs and lead us into a tyranny which becomes intolerable to human nature because of its disregard for human values. Knowledge and leadership must be indissolubly linked if disaster is to be avoided, and to no class of the community is there a stronger challenge in the present emergency than that addressed to scientific workers to declare with a united and unequivocal voice the potentialities of science in the evolution of a better world order and the lines upon which a systematic policy can be evolved.

### Horrors of the Next World War

*What would be the Character of a New War?*

Enquiry organised by the Inter-Parliamentary Union Pp xviii+411 (London P S King and Son, Ltd, 1931) 16s net

THE appearance of this volume is opportune in view of the Disarmament Conference now sitting, it contains eighteen articles contributed by eminent writers of various nations, mostly military men or university professors. Four of them are written by Frenchmen, three each by Englishmen and Germans, and others by men born in Sweden, Japan, Denmark, Switzerland, Russia, and Greece. Each author was evidently assigned a certain aspect of modern warfare, except that in some cases there are several articles on the same subject, but this plan has some disadvantages, because it was no one's duty to sum up the often conflicting conclusions, or to consider specially the fundamental nature of war. It was neglect of this last, or a too hasty generalisation from the character of a few recent conflicts, that led to the disillusion of the War of 1914-18 and of the subsequent conferences and conventions. Major Bratt and Lieut Sergel, of Sweden, do, however, discuss the matter in the first four pages of their paper on aerial weapons and future war, and Prof Politis (of Greece), in the final article dealing with the future of international law on warfare, says a few words on the subject.

The object of war is, of course, to defeat the enemy so effectually that he must sue for peace, and the best way to do this is to destroy a great part of his armed forces, so that he shall feel that further struggle is useless. If, however, the state of armaments be such that the powers of defence are greater than those of offence, mobile warfare becomes practically impossible, and then the invading army may make war upon the civil population, so that their miseries may induce an overwhelming desire for a cessation of hostilities. This is what happened in the Middle Ages, when the fortifications of the towns were able to withstand the assaults of hostile armies. Except in England, the sufferings of the ordinary people were terrible in every part of Europe in spite of the fact that Christian principles were professed far more then than now. In the eighteenth and nineteenth centuries artillery had reduced the value of fortresses, with the result that wars were of comparatively short duration, and were confined to the armed forces. The peoples were not affected to the same extent in this period, and a body of law on

warfare grew up in the belief that this was the normal nature of war

In the War of 1914-18 the development of railways and other modern means of transport rendered it possible to keep so many soldiers in the field that the whole line between the conflicting nations could be fortified. So, after the first brief attempt to settle the dispute by mobile warfare, it settled down to a state of siege. In the last years of the War the improvements in aeroplanes, and the increase in their numbers, rendered it possible to attack the civilians far from the front, and this was consequently done. At the same time naval warfare degenerated into attempts at blockade, and each side tried to starve out the other—men, women, and children.

As regards the next war, some of the writers are of opinion that it would resemble the last. For example, General Réquin (of France) sums up his article on modern developments with the words. "The general military character of a future war would largely resemble that which the war of 1914-18 assumed in its last phase." Others, however, advance good reasons for thinking that it would be very different and probably much more terrible. General Fuller, in his article on the mechanisation of warfare, prophesies that the campaigns of the future will be settled mainly by fleets of tanks, which will be manned by comparatively small armies of highly trained men. Large masses of infantry and artillery will, nevertheless, still be required to occupy the territory conquered, or to defend their country against invading tanks. It is likely that at the commencement of hostilities neither side will have a sufficient number of these mobile forts to bring matters to a decision, but the course of events will soon cause them to be built. The side which first acquires a superiority in this arm will win.

The other important new factor will be the enormous numbers of aeroplanes. According to Bratt and Sergel, the first objective of the air force will be the corresponding force of the enemy, including his aerodromes. The second will be the enemy's land forces, upon which, however, they will not have much direct effect. If the combined action of the land and air forces does not succeed in destroying the enemy's army in a short time, part of the air force will be used to attack the enemy's centres of industry with the hope of paralysing his war effort. In this the civilians must suffer severely, even if the bombing be not carried out with the deliberate object of striking terror into them. Chemical warfare is not likely

to have a decisive influence on the struggle, but will add to its horrors. Prof Politis quotes the following description by Prof Noel Baker of what is likely to happen.

"Aeroplanes light fires that cannot be extinguished, setting whole districts aflame, illuminating the town, and thus making it impossible to take shelter. Bombs blow up the public buildings at the defence posts. The people are forced to take refuge in the streets. Then come the gases which in their present form, are fatal whatever part of the body they touch. These gases, heavier than air, penetrate everywhere, into cellars, into the underground railways, permitting no escape. A bombardment of a few hours over Paris, Berlin, London could make at least 500,000 victims."

There is no reason to think that this picture is over-drawn, and indeed there are other similar ones in the book. Nearly all the eighteen writers are of the opinion that the agreements not to use aeroplanes for bombing civilians and to renounce chemical warfare will become 'scraps of paper' when war breaks out unless their use can be prevented. But it would appear to be less difficult to stop war altogether. In the last sentence of the volume Politis says: "The real policy of peace should be to prevent war, not to humanise it. Failing such a development of public opinion the wars and armaments will become impossible, it is doubtful whether our civilisation can survive."

ARTHUR MARSHALL

### The Dynamics of Wind

*Manual of Meteorology* By Sir Napier Shaw, with the assistance of Elaine Austin. Vol. 4. *Meteorological Calculus, Pressure and Wind*. (A revised edition of Part 4, 1919.) Pp. xx + 360 + xi. (Cambridge: At the University Press, 1931.) 30s. net.

METEOROLOGISTS the world over will be pleased that Sir Napier Shaw, the doyen of their international conferences, has been able in spite of advanced years to finish and revise, with the very efficient help of Miss Elaine Austin, his elaborate treatise on meteorology.

In meteorology elaboration is inevitable. School boys have confidence in their calculations when the result is a simple number. Einstein has somewhere remarked that he was guided towards the theory of relativity partly by the notion that the universe is essentially simple. R. H. Fowler has been heard to say that of two theories the more elegant is probably the more physically correct. If such eminent physicists could be persuaded to attend to meteorology

logy, that science would be greatly enriched, but they would probably be forced to abandon the faith that Nature is essentially simple

This volume, which is more than twice as long as its 1919 edition, and includes many references to recent publications, bears the title "Meteorological Calculus, Pressure and Wind". Entropy also is frequently considered in its connexion with wind. The subject matter is arranged more or less in the following sequence: (1) A verbal account of the forces concerned. (2) Photographs of typical anemograph traces. (3) The general dynamical and other equations for a compressible fluid covering a rotating earth. (4) A review of the attempts that have been made to use fairly general equations. (5) The geostrophic approximation in which the pressure gradient is regarded as balanced by the Coriolis force due to the earth's rotation. (6) The effect of turbulence on the mean direction and velocity of the wind near the ground. (7) The effect of turbulence on cloud sheets. (8) Observations obtained by watching free balloons through theodolites. (9) The effect of horizontal temperature-gradient on the change of wind with height, including an elegant theory. (10) The graphic analysis of atmospheric motion. (11) A second approximation including not only the earth's rotation but also the curvature of the track on the map. (12) Cyclones and anticyclones, conventional and real, but with attention chiefly to their rotation. (13) The meeting of tropical with polar air and the resulting conversion of heat energy into motion, with the formation of cyclones. (14) Under the motto—

We look before and after  
And pine for what is not—

the book ends with a retrospect of the four volumes of which it is the last

There is in some textbooks a sort of clarity which is attained by mentioning only the simplest types of phenomena, by leaving out all inconvenient qualifications and by looking at the subject steadily from one point of view. The reader will not find that sort of clarity in this book. Instead, phenomena are considered in their actual complexity, qualifications are made prominent and the point of view wanders among the observational, mathematical, historical, administrative, and poetical aspects. Portions of information which seem to have come from one chapter have diffused into other chapters, like cumuli into the blue sky. Sir Napier "bloweth where he listeth", and it would be hard to tell whence he cometh or whither he goeth, were it not that there is a full index and a summary of the contents of the four volumes

Sir Napier has endowed meteorology with a number of admirably descriptive and euphous technical terms, including "geostrophic" and "tephigram". The reader should be forewarned of the queer notation "*bb*" for barometric gradient. According to V. Bjerknes an atmosphere is termed 'barotropic' if the density is either constant or *any* function of the pressure only. This term is valuable because barotropic conditions are often assumed in the older mathematical theories but seldom occur in observational data. It is regrettable that on p. 298 'barotropic' is wrongly defined by being restricted to the *special* function  $p\rho^\gamma = \text{constant}$ .

This volume is entitled a "calculus", but words predominate. The mathematical inquirer will find in it his observational raw material discussed by authors of wide experience, with the aid of about eighty diagrams. He will also find plentiful warnings against the approximations to which mathematicians are disposed, several important theories fully and clearly set out, and many useful references to mathematical papers old and new. But unsatisfying or mysterious summaries will probably drive him to the original works.

### Homer's Natural History

*Die homerische Tierwelt*. Von Prof. Dr. Otto Korner. Zweite, für Zoologen und Philologen neubearbeitete und ergänzte Auflage. Pp. iv + 100. (München: J. F. Bergmann, 1930.) 6 60 gold marks.

THERE is no one quite like Homer to those who love him. He is so simple yet so great, so easy to understand and withal so noble, that a shadowy friendship, firm and intimate at last, grows up between us; there are few great poets who can make friends as he can with mortal men. When one does get to know Homer the friendship lasts a lifetime, and one comes to feel what Mr. Pope calls "a certain complacency in his company". Hard by my own door a scholar lives who knew his Homer by heart, every single word of him, a lifetime ago, and who has kept his friendship from youth to age, and in just the same way a certain old physician of Rostock, Prof. Otto Korner, has had Homer for a close and lifelong friend.

Fifty-two years ago, Prof. Otto Korner published, and now he has revised and enlarged, this little book on Homer's natural history, later on he wrote on Homer's and Hesiod's knowledge of the bee, and only a couple of years ago he wrote, fully and learnedly, on Homeric medicine and surgery. These cover and include Homer's

anatomy and physiology, which, as Daremberg has told us, are as admirable as those of the "Corpus Hippocraticum." In this last little book Dr Korner told us, for example, just how, when Idomeneus had thrust his lance right into the heart of Alcathous, the last heart-beats caused the shaft to quiver or what that Nepenthes was which Helen put into the wine-cup, or how, in August and September, the Dog-star brought malaria (πολλὸν πυρετόν) to mortal men.

Natural history never stands by itself in Homer, it lies in the background of the picture, and comes in by way of apt allusion and similitude, it is drawn from an unspoiled land, where wild life was plenteous, and wolf and eagle almost as familiar as grasshopper and nightingale. So the poet's allusions were all within the common experience of his hearers, and sometimes a phrase was enough to indicate them, and sometimes they were painted in with loving elaboration. Blind as he was, there was little Homer did not know, he knew the cuttlefish and his suckers, and how the wolf on the mountain-side has a narrow tongue and laps like a dog. Here at random are a few of the old familiar similes.

When Sarpedon and Patroclus quarrelled they looked like two angry vultures on the ground, rushing together with flapping outspread wings,

They cuff, they tear, they raise a screaming cry,  
The desert echoes and the rocks reply.

In a famous passage (Milton knew it well) the Trojan host is marshalled like the migrating cranes, noisily but in order, it is one of the noblest spectacles in ornithology. Penelope bids her returned but yet unrecognised husband sit a while longer and pass the evening hours, for then she sits alone and grieves—as does the nightingale. Then comes a dreadful story of the wanton handmaidens and how they met their punishment, and beat the air with twinkling feet,

Thus on some tree, hung struggling in the air,  
The doves and thrushes flap their wings in air.

A more cheerful picture is that of the old men sitting in the gate,

Chiefs who no more in bloody fights engage,  
But wise thro' time and narrative with age,

wisely or no, they chatter all day long—like the cicadas chirruping in the sun. The old men's garrulity, their delight in company, the thin sound, the high treble, of their old voices, their pleasure in the sunshiny day, are all told imitatively, and almost in a word. A very different picture is that of Achilles' Myrmidons on the warpath, a grim, terrific, formidable band, wolf-like, with lolling

tongues, gorged but insatiate, it is the savages and most terrible picture in all Homer.

Dr Korner does not write eloquently or poetically, like most classical commentators his job is to look for the prose behind the poetry but he deals very competently with his theme. There are a few stories which he does not tell. He knows that Odysseus is compared, in a certain passage, to a ram—a dubious comparison, but he does not help us (I cannot recall a single commentator who does) by explaining that this particular ram (κτίλος) is the old wise leader of the flock, *dux ovium*, trained to walk beside the shepherd as Odysseus walked by Agamemnon's side, and to be followed, trusted, pampered, and obeyed.

### Drugs of Addiction

- (1) *A Review of the Effects of Alcohol on Man* Pp 300 (London: Victor Gollancz, Ltd., 1931) 8s 6d. net
- (2) *The Alcohol Habit and its Treatment* By Dr Walter E Masters Pp xvi+190 (London H K Lewis and Co, Ltd, 1931.) 6s net.
- (3) *Dangerous Drugs the World Fight against Illicit Traffic in Narcotics* By Arthur Woods Pp vii+123. (New Haven, Conn Yale University Press, London Oxford University Press 1931) 9s net

THESE three volumes deal with certain aspects of the medical and social problems presented by habit-forming drugs. (1) The first gives an account of the physiological and pathological effects of alcohol upon the human body and mind. It is the work of a number of different authors, and has been edited by a small private committee comprised of persons interested in the drink problem. Its aim appears to be to give a scientific account of the uses of alcohol as a food and a drug, and of the pathological results of alcoholism, chapters are devoted to the mental effects of alcohol, to its relationship to mental disorder, and to its possible racial effects. The book may be recommended as a balanced account of the subject, in which the legitimate uses of alcohol are carefully described and the effects of its abuse are neither minimised nor exaggerated.

(2) The second book is supplementary to the first. In its earlier chapters it covers much the same ground in brief, but the greater part of the book is devoted to the treatment of chronic alcoholism. Dr Masters considers that a real cure is impossible, the criteria of cure being that the desire for the

alcoholic euphoria is abolished and the capacity for moderate indulgence regained, without the least desire for an excess. On the other hand, a number of addicts can be converted into total abstainers and in this sense cured the rest relapse. The author includes a chapter on certain legal considerations of drunkenness.

(3) Drugs of addiction other than alcohol, morphine, cocaine, and their derivatives, are dealt with in the third book, and from an entirely different aspect. After a short account of the effects of these drugs upon the system, including the mental effects for which they are taken, the author turns to the sociological aspects of the question, including the traffic in narcotic drugs and the steps already taken under the auspices of the League of Nations to limit their manufacture and distribution. The book gives a highly interesting account of the tricks used by the traffickers in distributing the drugs; the real remedy appears to be limitation of manufacture to legitimate medical requirements, but the League has not yet persuaded all manufacturing countries to adopt vigorous measures of control. Perusal of this little book should increase the demand for firm action in those countries which have not yet adopted adequate limitation of manufacture or control of distribution.

### Short Reviews

*Penrose's Annual the Process Year Book and Review of the Graphic Arts* Vol 34, 1932. Edited by William Gamble. Pp xv+126+54+105 plates. (London Percy Lund, Humphries and Co, Ltd, 1932) 8s net.

"PENROSE'S ANNUAL" is always a happy hunting-ground to anyone interested in the printing of books and pictures. This year's volume is a rich collection of work of all kinds, much of it very beautiful. Perhaps the outstanding examples are those in photogravure, both monochrome and colour. We are by this time thoroughly accustomed to the fifty-year-old 'half-tone' process, and it is therefore interesting to find that even in this process advance is being made: the successful making of blocks for half-tone reproductions in colour has depended very much on the judgment and skill of the fine etcher. The recent introduction of a special colour chart and set of dot-size samples has, however, reduced the fine etcher's work almost to a certainty—judgment and experience are largely replaced by comparison with standard dots. The general trend in the printing industry is, indeed, strongly towards standardisation of method. A new development during 1931 has been the formation of a Printing Industries Research Association. Its work so far has apparently been mainly consultative, but experimental work has begun on several problems. S O R

No 3250, Vol 129]

*Molds, Yeasts and Actinomycetes a Handbook for Students of Bacteriology* By Prof A T Henrici. Pp x+296. (New York John Wiley and Sons, Inc, London Chapman and Hall, Ltd, 1930) 17s 6d net.

As our knowledge increases, the part played by fungi as distinct from bacteria in the soil, in the spoilage of food, and in disease processes in animals and in man, is becoming more recognised. A book dealing in some detail with these organisms is therefore likely to be of considerable use for reference purposes. Sufficient information is given on the morphological side to enable the more important species to be identified, whilst the chemical aspect of their behaviour is adequately considered, as well as the industrial application when such is of moment.

This book is an American production, it is well arranged and printed in clear type, and particularly well illustrated. Ample references to the literature are given at the end of each chapter.

*Das Wasser in der Natur und im Dienste des Menschen* Von Dr Hans Heinze (Der Weg zur Natur) Pp xi+164. (Freiburg im B Herder und Co, G m b H, 1930) 3 60 gold marks.

To discuss in any detail the occurrence of water in its many natural appearances and in its human relationships as well, would be impossible in so small a book. Therefore its eleven short chapters deal in a popular and simple manner with the more striking characteristics and influences of rain—of seas, lakes, and rivers, of snow and ice. Plant life enters the story when the fall of the leaf in autumn exemplifies the effect of a shortened water-supply, and microscopic animal life is revealed as the marvellous content of water-drops, but here the illustrations are very crude. A third of the book deals with drinking water, mineral waters, and water as a source of power, and, in connexion with each, with the apparatus by which man has harnessed them for his own purposes.

*Applications of the Absolute Differential Calculus.* By Prof A J McConnell. Pp xii+318. (London, Glasgow and Bombay Blackie and Son, Ltd, 1931) 20s net.

THIS work fills a distinct gap in the mathematical student's library by giving an account of tensor methods in their application to the more elementary problems of geometry and physics. Of the four parts into which the book is divided, the first deals in a clear and simple manner with the fundamental ideas of tensor theory. In the second part these ideas are applied to algebraic geometry. The third part introduces the absolute differential calculus proper, the differentiation of tensors, and develops the application to differential geometry. In the fourth part the author deals with applications to dynamics, hydrodynamics, electricity, and elasticity. There is a large collection of examples which greatly enhances the value of the book to the student.

## Hydrogen Liquefaction Plant at the Royal Society Mond Laboratory

By Prof P KAPITZA, F.R.S., and Dr J D COCKCROFT

**I**N the Royal Society Mond Laboratory which is now under construction at Cambridge, in addition to the apparatus required for producing intense magnetic fields, a plant for cryogenic work will be installed. We have developed as a first instalment of this apparatus a hydrogen liquefier which differs from existing liquefiers in that it allows hydrogen of a lower degree of purity than the normal to be used for liquefaction. We propose in this article to give a brief description of the liquefaction apparatus, and later to publish a more complete account.

As is well known, the only method used at present for the liquefaction of hydrogen is essentially the same as that employed originally by Dewar in 1898, and is based on the Joule-Thomson effect combined with a thermal regenerator. In order to obtain a positive Joule-Thomson effect for hydrogen a preliminary cooling with liquid air is required. The principal difficulty encountered in liquefying hydrogen in large quantities is due to the impurities present in the gas, unless extremely pure hydrogen is used, these impurities solidify at the temperature of liquid hydrogen and block the tubes in the regenerator and stop the circulation of the gas. The seriousness of this effect can be shown from a numerical example. The purest commercial hydrogen available in Great Britain is 99.5 per cent pure, 3.9 cubic metres of gas are required to produce 5 litres of liquid hydrogen, and the impurities—chiefly air—when solidified have a volume of about nineteen cubic centimetres. Their deposition is thus quite sufficient to block the small bore tubes of the regenerator, and special precautions have to be taken to avoid this difficulty. In the method developed by Kamerlingh Onnes at Leyden, a preliminary purification of the hydrogen to a high degree of purity is carried out, and steps are taken to save the gas after it has been used for experiments. Another method introduced by Meissner is to make a special trap in the hydrogen circulation in such a way that in it the greater part of the impurities are condensed, the liquefaction is stopped at intervals to allow the trap to be warmed by a special electrical heater and emptied.

In our liquefier we have adopted a different principle which allows us to use the apparatus continuously even with commercial hydrogen. The method is as follows. Two hydrogen circuits are used in the liquefaction process, one circulation is similar to that used in ordinary liquefiers, but is completely closed, in it about 0.7 cubic metre of purified hydrogen is compressed to 160-170 atmospheres, and after preliminary cooling in liquid nitrogen at reduced pressure passes through a regenerator spiral and then expands to normal pressure, thereby cooling down a 'condenser' to liquid hydrogen temperature, after which it returns through the regenerator to the compressor. In the second circuit we use ordinary commercial

hydrogen, which is reduced to a pressure of 3 atmospheres by means of a reduction valve from cylinder. This hydrogen is cooled down to the temperature of liquid nitrogen and is then passed directly into an 'exchanger' cooled by the first circuit. Since the liquefaction temperature of hydrogen at 3 atmospheres pressure is a few degrees higher than at normal pressure, it liquefies in the exchanger. The whole of the cooling down process, from the temperature of liquid nitrogen to the temperature of liquid hydrogen, takes place in the exchanger, so that all the impurities condense here and do not have a chance of being deposited in the tubes. The solidified impurities are heavier than the liquid hydrogen and remain at the bottom of the exchanger, which is large enough to retain all the impurities solidified in the course of a run.

The scheme of the liquefier is shown diagrammatically in Fig 1, and a photograph of the liquefier in Fig 2. The hydrogen in the closed circulation enters at tube 1, passes through the regenerator spiral A, and enters the container B containing liquid nitrogen at reduced pressure, from which it passes through the second regenerator spiral D, and then through the expansion valve E to the condenser F, where it is partially liquefied. When the condenser F is about one-third full, the liquid hydrogen passes through tube 6 to a spiral which

FIG 1

goes through the regenerator spirals D and A and passes back to the compressor through the outlet 2. The commercial hydrogen enters the tube 3 and passes only through the first regenerator circuit A, and the container B, and then passes directly into the exchanger G, where it meets the spiral cooled by the closed circulation and is liquefied at three atmospheres pressure. The exchanger G is continuously drained through the tube 4 passing through the condenser F as a spiral and leading to valve H, which controls the flow of liquid hydrogen into a Dewar receptacle. In passing through the spiral of condenser F, the liquid hydrogen is cooled through a few degrees from the temperature corresponding to liquefaction at three atmospheres pressure to the temperature of liquid hydrogen at atmospheric pressure. This prevents excessive evaporation when it is

drawn off into the Dewar receptacle. The exchanger *G* is filled with wire gauze which helps in the liquefaction. In the actual liquefier a double container is used for the liquid nitrogen. In one part the liquid nitrogen is evaporated at slightly reduced pressure and the evaporated gas passes up tube 5 of regenerator *A* and takes up sufficient heat to cool down the incoming hydrogen of the liquefaction circulation, in the other part the liquid nitrogen evaporates at a few centimetres pressure and passes away directly to the pump. (During a recent visit to Dr Simon's laboratory at Berlin, we have been informed that the same principle of

FIG 2

cooling hydrogen in two stages was used in his liquefier.)

The tubes used in the liquefier have a small cross-section and the gas is allowed to flow with high velocity. We find, as suggested by Meissner,<sup>1</sup> that the heat exchange can be calculated from Nusselt's formula.<sup>2</sup> From this formula it appeared that a good heat exchange could be obtained by using a high velocity of the gas, and this enabled us to reduce the length of the regenerator spirals very considerably. In our case the spiral *A* was about 2.5 metres long and the spiral *D* 5 metres. The high tensile strength of the copper-nickel alloy allows the heat capacity of the regenerator spiral to be considerably reduced. The whole apparatus is soldered into a copper vessel 26 cm in diameter

by 67 cm high, which is then evacuated. By the use of charcoal to absorb gases given off from the metal, a good vacuum can be maintained and a high degree of thermal insulation maintained without the use of glass Dewar vessels.

The new liquefier has the considerable advantage that the rate of liquefaction can be measured continuously by a flow meter placed before the inlet of tube 3. The flow meter will also indicate the moment when the gas begins to condense. An electrical flow meter is used. The hydrogen is passed through a thin-walled copper-nickel tube 20 cm long, which is heated in the middle by a platinum wire spiral. The cooling of this spiral depends on the rate of flow of hydrogen through the tube and is measured by its change of resistance. The spiral is made in two parts which form the two opposite arms of a Wheatstone bridge, the other two arms are also made of platinum, and are wound on the thick copper main tube, and thus are kept at the temperature of the inlet hydrogen. The apparatus is calibrated by separate experiments.

The liquefier has proved to be as efficient as ordinary existing liquefiers. The heat exchange is good, and the temperature of the return hydrogen and nitrogen at exit is only 10° below the temperature of the inlet hydrogen. 4-5 litres of liquid nitrogen are used for the initial cooling, and liquefaction starts 40-50 minutes after the beginning of the preliminary cooling. The liquefaction rate is 4 litres an hour, of which about twenty per cent is lost when the hydrogen is drawn off. The liquid nitrogen consumption is about 1.3 litres per net litre of liquid hydrogen. We normally produce 6 litres of liquid hydrogen in a single run, using commercial hydrogen, and have not up to the present had a single stoppage due to blocked tubes. The liquefier was made in our workshop by the laboratory mechanic, Mr. H. E. Pearson.

The compressor used for the work is a compact, triple stage, high speed (600 r.p.m.) machine which was specially built for us by Messrs Reavell and Company. The detailed design was worked out by Mr. J. Hendry. Special care was taken to ensure complete freedom from leakage, the space below the cylinders is connected to the compressor suction, and the piston rods are surrounded by oil-sealed glands which are fitted with leakage indicators. At full speed the compressor capacity is 25 cubic metres of free gas per hour, at present we are using it at reduced speeds giving a delivery of 16 cubic metres per hour.

The problem of storage of liquid hydrogen has been dealt with on new lines. It is well known that owing to the small latent heat it is difficult to store liquid hydrogen in an ordinary Dewar flask for more than a day. As described by Meissner,<sup>3</sup> the best containers, of a capacity of 6 litres, evaporate at the rate of 15 gm (200 c.c.) of hydrogen an hour, these containers have a specially good vacuum and silvered surfaces to prevent radiation losses, which are the most important source of loss of cold. In order to diminish these radiation losses further, we have worked out a design for a Dewar flask which has all the advantages of the

method of keeping the liquid hydrogen container immersed in liquid air, without the disadvantages and technical difficulties which occur if this method is used on a large scale. A drawing of the flask is shown in Fig 3. It consists of a twin flask, flask

FIG 3

1 contains liquid air, and flask 2 liquid hydrogen. The inside of flask 1 is connected by means of a copper rod 3 to a copper shield 4 which surrounds the container of flask 2. The liquid air cools the shield 4 by thermal conductivity, and the radiation losses from the liquid hydrogen are considerably reduced. The hydrogen flask has a capacity of 5 litres and the liquid air flask holds 2 litres. The

evaporation of hydrogen is about 2.5 gm. an hour, which is about seven times smaller than for ordinary flasks, and enables the liquid hydrogen not required for immediate use to remain in the flask for five days. The consumption of liquid air is about 1.7 litres per day. A picture of the flask will be seen in Fig 2 standing beside the liquefier.

Another flask is now being constructed in which the radiation will be further reduced by silvering the inner surfaces, thereby increasing the efficiency of the flask still further. The flask was manufactured for us by Messrs Siebe Gorman and Co., Ltd.

The remaining equipment of the Laboratory is on the usual lines, and all the known precautions against explosion are employed, flame-proof mining type motors being used for the compressor drive and all open switchgear placed in a separate room. Besides the usual precautions we have introduced one more, which consists of a standard alarm lamp as used for showing the presence of coal gas in mines. This indicator is manufactured by Messrs The W. R. Patents, Ltd. Should a leak occur, and the concentration of hydrogen in the room reach a value of more than one per cent, the lamp operates a relay which automatically stops the machines, and throws the windows open at the bottom and the top of the rooms where the liquefier is in operation, thus providing a complete air circulation.

We were enabled to construct this plant by a special grant made by the Department of Scientific and Industrial Research.

### Diagnosis of Smallpox \*

FOR adequate control of infectious disease, early and accurate diagnosis is of great importance, but clinical differentiation is not always easy in the early stages. Thus smallpox, even of the severe type, may be mistaken for chickenpox. Some years ago M. H. Gordon described a 'flocculation' test for smallpox, which was later investigated by W. L. Burgess, J. Craigie, and W. J. Tulloch. The last two authors have now extended and amplified the earlier observations. The technique of the test is, in brief, as follows: crusts obtained from the pocks are dried and finely powdered, the powder is extracted with ether and then with saline for some hours, the mixture is frozen, thawed, and centrifuged to remove particulate matter. Series of dilutions of the extract are made in saline. To one antiovaccinia serum is added, to the other normal rabbit serum, and both sets are incubated for about 18 hours at 45°-55° C. Flocculation occurs in the first series at high dilutions of the extract if the crusts were obtained from a case of smallpox, but is not seen in the second series to which normal rabbit serum was added.

The authors carried out an investigation of every step in the test so as to obtain the best conditions

thus it was found that more satisfactory results were obtained when the concentration of antiserum was kept constant and that of the antigen (crust extract) varied than when the converse system was employed. For the extraction of the crusts, 0.9 per cent sodium chloride solution was better than weaker concentrations and much more satisfactory than a phosphate buffer solution. In the latter the reaction shifted towards the acid side, whereas that of the saline extracts is remarkably stable. It is essential to carry out the flocculation test at about pH 7. At pH 6 or 8 non-specific sedimentation is liable to occur. The preliminary extraction with ether removes certain substances which may obscure the test and also reduces the tendency to anomalous flocculation. It has been found further that the flocculable substance is fairly intimately connected with the euglobulin fraction of extracts although it can be to some extent separated therefrom when the flocculable substance has been destroyed infectivity has also disappeared, but the latter can be markedly reduced without affecting the former. The purified euglobulin fraction is not very stable to heat but is fairly stable to low concentrations of phenol. It is possible to detect by the flocculation test so little as 0.0000005 gm. of purified flocculable material.

The flocculation test is positive in smallpox

\* Medical Research Council Special Report Series No. 156. Further Investigations on the Variola-Vaccinia Flocculation Reaction. By J. Craigie and W. J. Tulloch. Pp. 129. (London: H.M. Stationery Office, 1931.) 3s. net.

(mild or confluent), dermal vaccinia, neurovaccinia, or generalised vaccinia of the rabbit. Out of 195 tests on human material only three (cases of variola minor) gave apparently erroneous results. All crusts from cases of chickenpox were negative. The test is therefore specific and indicates the identity of the infecting virus of smallpox with that of vaccinia (or cowpox, the attenuated virus which is used to develop immunity to smallpox in human beings by 'vaccination'). These results also show that the secondarily infecting bacteria present in dermal material have no influence on the reaction, this conclusion was confirmed by further direct experiments. Thus it was found that crust-extracts removed the flocculating property from anti-vaccinia serum, but failed to remove the staphylococcal agglutinating bodies from antistaphylococcal serum, and that absorption with suspensions of secondarily infecting bacteria had no effect on the flocculating properties of anti-vaccinia serum although such absorption rendered inert the anti-sera specific to the secondarily infecting organisms.

An antiserum such as is used for the flocculation test appears to exert a specific antibody action on the virus *in vitro*. After four hours incubation at 37° C of a mixture of serum and virus the latter is inactivated or destroyed, since no lesion is produced on dermal inoculation. Destruction is theoretically unlikely and probably does not actually occur since infection may be produced if inoculation is made into the rabbit's testes.

On the other hand, evidence was obtained that passive immunity to vaccinia could be produced in rabbits and guinea-pigs by the injection of anti-vaccinia serum possessing flocculating properties. The immunity of the animals was tested by dermal, testicular, and intravenous inoculation of virus; the results did not depend on the serum or strain of virus used.

As a natural sequel to the above results, attempts were made to produce immunity by the use of virus sensitised with antiserum. It was found that such a mixture, although failing to 'take' on dermal inoculation, produced, on subcutaneous injection into rabbits, a very high degree of immunity. The importance of this observation lies in the fact that it may be possible to produce immunity in human beings by this method without the risk, small though it is, of the development of the sequelæ, such as vaccinal encephalitis, which occasionally follow ordinary 'vaccination'. The theoretical objection to the use of sensitised virus is that although the antiserum may control the infection at the site of injection, it may be powerless to do so if the virus is disseminated. The authors are carrying out further investigations on this point. In any event, the results of the experiments on the production of passive immunity suggest that it might be possible to immunise smallpox contacts so that the disease would be aborted even in circumstances when vaccination might fail to prevent infection.

### Obituary

MR LOUIS BRENNAN, C B

BY the death of Louis Brennan on Jan 17, at Montreux, Switzerland, Great Britain loses an inventor whose name was once very widely known. Born at Castlebar, Ireland, on Jan 28, 1852, Brennan at an early age went to Australia, and it was while working as a watchmaker in Melbourne that he conceived the idea for a torpedo which could be fired and controlled from a fixed position.

Assisted by a member of the staff of the University of Melbourne, towards the end of the seventies of last century Brennan succeeded in arousing the interest of Government officials, and in 1880 the Admiralty appointed a committee of naval officers serving on the Australian station to report on the torpedo. Their report being favourable, Brennan was brought to England, and as the torpedo was considered very suitable for the defence of creeks and harbours, the matter was taken up by the War Office, Brennan being attached to the Royal Engineers at Chatham, and a torpedo factory being built at Gillingham. Brennan was at first given a retaining fee of £5000 and a salary of £2000. He superintended the factory for many years, and from 1896 until 1907 was retained as consulting engineer.

Luke Whitehead's automobile torpedo, Brennan's machine was fish-shaped and had fins, horizontal and vertical rudders, hydrostatic depth control, and double propellers, but it was driven and con-

trolled by two wires running over drums driven by a steam engine in the firing station and connected with other drums in the body of the torpedo.

At Gillingham, Brennan began his work on the monorail locomotive with gyroscopic stabilisers. His model, now in the Science Museum, South Kensington, was described in the technical press in 1907, and a public trial of his car took place at Gillingham on Nov 10, 1909. The car was 40 ft long, 10 ft wide, and 13 ft high, and had a wheel base of 20 ft and a weight of 20 tons. It ran on a single rail track, which included a circular path 200 yards round, and successfully carried a party of 40 persons. It was fitted with two petrol engines driving electric generators supplying current to the driving motors, and to two large gyroscopes which preserved the balance of the car in all circumstances. Each gyroscope had a wheel weighing three-quarters of a ton, revolving at 3000 r.p.m. in a casing from which the air was exhausted. On the day of trial, owing to one of the generators being out of action, a speed of only 7 miles an hour was attained, but the designed full speed was 35 miles an hour. Brennan himself envisaged a monorail car 150 ft long and 25 ft wide travelling at about twice the speed of existing railway trains, but his invention did not lead to any development.

During the War, Brennan served with the Ministry of Munitions and later with the Air Ministry, and

experimented with a helicopter, but much of his work was of a confidential nature. He received the honour of C B in 1892, in 1906 was made a honorary member of the Royal Engineers' Institute, and in 1922 a foundation member of the National Academy of Ireland

#### MR C J MERFIELD

THE tragic death of Mr Merfield as the result of a motor accident occurred on Jan 23, 1931, but it did not become known in England until later. He was a very zealous and active worker, and undertook a large number of extensive astronomical computations. In his early career he was a surveying engineer, but even then he computed the orbits of comets in his spare time, the orbits of comets 1897 I, 1901 I, etc., were published in *Astronomische Nachrichten*. The last was a very bright southern comet, Mr Merfield's elements, which indicate a period of 39,000 years, are accepted as definitive.

A few years later, Mr Merfield joined the staff of the Sydney Observatory, he moved to Melbourne Observatory in 1908, and became chief assistant there in 1919, a position which he held until his death. He continued his work on comets, deducing an accurate orbit of Halley's comet from the early observations, and tracing the perturbations of the Pons-Winnecke comet for a long period, including its near approach to the earth in 1927. In his earlier years he had studied under Dr R T A Innes, it was doubtless at the suggestion of the latter that he performed the laborious task of computing the secular perturbations of Eros, Ceres, and Iris, these were published in *Astronomische Nachrichten* in 1907 and 1909.

Mr Merfield was also interested in eclipses, and computed their circumstances in Australia and the neighbourhood, he observed the total solar eclipses of 1901, 1910, and 1911. His son, Mr

Z A Merfield, is the Australian representative on the Solar Eclipse Committee of the International Astronomical Union. We are indebted for many of the above details to Mr J A Moroney, president of the Astronomical Society of Victoria, of which Mr Merfield was the first president on its formation in 1922.

PROF HOLLAND CROMPTON, formerly professor of organic chemistry at Bedford College, London, who died on Dec 22, 1931, was born in Preston, Lancashire, on April 30, 1866. He attended school in Stuttgart and later studied chemistry under Prof H E Armstrong at the City and Guilds Institute. In 1888 he was appointed lecturer and head of the Department of Chemistry at Bedford College, London, in succession to Spencer U Pickering. He held this post until 1919, when the department was divided, and from that date until his retirement in 1927, on account of ill-health, he was head of the Department of Organic Chemistry. Crompton never enjoyed robust health, and in his later years it became steadily worse. He will be remembered by both organic and physical chemists on account of his work on acenaphthene, atomic energy and the specific heat of gases, molecular association and molecular magnitudes, osmotic pressure and the electrolytic dissociation theory.

WE regret to announce the following deaths

Prof Clarence L E Moore, professor of mathematics in the Massachusetts Institute of Technology, Cambridge, Mass., who devoted particular attention to the geometry of the sphere and circle in space, on Dec 5, aged fifty-five years.

Prof R Stenhouse Williams, first director of the National Institute for Research in Dairying, Shinfield, Reading, and research professor in dairy bacteriology in the University of Reading, on Feb 2, aged sixty years.

### News and Views

#### Determinism Defined

SIR ARTHUR EDDINGTON's characteristically fascinating address on "The Decline of Determinism", which we publish as our Supplement this week, will be welcomed as a clear, unequivocal statement, by a leading authority, on a question which, even among the many revolutionary aspects of the new physics, holds a pre-eminent place for importance and interest. Such a statement is the more necessary because of the almost universal tendency for discussions of determinism to be concerned at bottom with words rather than ideas, and Sir Arthur has quite properly begun by stating definitely what he means by the determinism which he holds has declined. His thorough analysis leaves little room for disagreement, but many will wonder whether he has not achieved a Pyrrhic victory by conceding to the determinist the substance of his doctrine and destroying only the shadow. "The rejection of determinism is in no sense an abdication of scientific method", and "indeter-

ministic or secondary law . . . can be used for predicting the future as satisfactorily as primary law". In other words, Sir Arthur does not allow that the first Morning of Creation wrote what the last Dawn of Reckoning shall read, but he allows that it might have read what the last Dawn shall write. Even the most perfervid determinist will scarcely ask more. Furthermore, he acknowledges that he does not know whether Dirac, whose book "goes as deeply as anyone has yet penetrated into the fundamental structure of the physical universe", is a determinist or not. It would seem, therefore, that the determinism in question cannot be of much importance even in physics.

#### Physical Inference and Prediction

APPARENTLY, however, in spite of the unqualified statement concerning prediction quoted above, Sir Arthur denies that we can predict the behaviour of electrons more certainly than that of horses, and the importance, to all but the physicist, of the "decline

of determinism " therefore depends on the recognition of electrons as bodies co-equal with ordinary physical objects. To establish this he claims that since physical objects, as well as electrons and such particles, are all 'inferences', they differ only in degree and not in kind. We must not, however, be deceived by words. Objects which we see and handle may be, as he says, as inferential as an undiscovered planet inferred from irregularities in the motion of Uranus, but the inferences are of different kinds, otherwise, why, when a planet was seen in a different position from that inferred from the irregularities, was it *without question* preferred to the 'undiscovered' inferential planet? There was not even an instinctive estimate of the 'degree' of validity to be attributed to the two 'inferences'. Unless Sir Arthur assigns to "direct observation" a status essentially different from that of rational deduction, it is difficult to see how his position can be "in no sense an abdication of scientific method". All this, however, does not affect determinism in relation to physical objects, and it is to be hoped that Sir Arthur's plain statement will do much to remove the widespread delusion that modern physics has revealed a universe of unrestrained caprice.

#### Centenary of Octave Chanute

ON Feb. 18 occurs the centenary of the birth of the distinguished American engineer Octave Chanute, who by his experiments on gliding made in his later years, and by his writings on flight, gained for himself a place among the chief pioneers of aviation. Born in Paris on Feb. 18, 1832, he was the son of a professor of history who in 1838 removed to the United States to become a vice-president of the Jefferson College in Louisiana. There and in New York young Chanute attended school and, in his own words, became thoroughly Americanised. Leaving school at the age of seventeen, he entered the service of the Hudson River Railroad Company, and during the next four years gained considerable engineering experience. He next spent ten years on various railroads farther west, and from 1863 until 1867 was chief engineer of the Chicago and Alton Railroad. In 1868 he built the first bridge over the Missouri at Kansas City, in 1873 became chief engineer of the Erie Railroad, and about ten years later established himself as a consulting engineer in Kansas. He had already served on the commission of engineers which led to the building of the elevated railways of New York, and at Kansas he was responsible for the construction of the Sibley Bridge over the Missouri, and for the Mississippi Bridge at Fort Madison, Indiana. He retired to Chicago in 1889 after some forty years' work, much of which had contributed to making the railway system of the United States the most extensive in the world.

CHANUTE's interest in flight was first aroused in 1874, but it was not until he was nearly sixty years of age that he was able to devote himself wholeheartedly to the study of the subject. In 1891 he published his first work, "Aerial Navigation", and this was followed in 1894 by his "Progress

in Flying Machines", a work of great historical value. He had carefully examined the results of the experiments made by Otto Lilienthal in Germany, and just before that pioneer's death in 1896 had secured a Lilienthal glider and had begun his own experiments on the 90 ft sand-hills in Dune Park, near Lake Michigan. Finding the Lilienthal machine unsafe and treacherous, Chanute built a glider with five superimposed planes, which was afterwards altered to a quadruplane and then to a triplane. From these was evolved "the famous Chanute biplane of novel and exquisite design". One important feature introduced by Chanute was the means of moving the wings in a fore and aft direction to maintain balance, thus obviating the necessity for violent body movements. The experiments begun in June 1896 were continued until September, but after then were never resumed. An account of them was given in a paper published in the *Journal of the Society of Western Engineers* in 1897. While abandoning experiments, Chanute, although then sixty-four years of age, retained his enthusiasm for everything connected with flight, assisted and encouraged Wilbur and Orville Wright, and when an old man wrote his "Recent Progress in Aviation". He died at Chicago on Nov. 23, 1910, at the age of seventy-eight. Chanute possessed the truly scientific spirit, and was an acute observer as well as a gifted inventor. Courageous and generous, his character caused him to be both respected and honoured.

#### The Earthquake in Cuba

ON Feb. 3 a series of destructive earthquakes, beginning at 2.40 A.M., ruined about one-third of the city of Santiago, at the east end of Cuba, including the cathedral and many important buildings. The number of persons killed is reported as twelve, and the number of wounded as about three hundred. The earthquake was recorded at Kew Observatory as a disturbance of moderate intensity. The first impulses arrived at 6h. 26m. 45s. A.M. (G.M.T.), and the earthquake must have occurred at 6h. 16m. The neighbourhood of Santiago has long been known as one of the most active earthquake centres in the West Indies. The city was founded in 1514, and since then there have been great destructive earthquakes in 1624, 1678, 1766 (the greatest of all Cuban earthquakes), and 1852. Though the full extent of the damage is not yet known, the recent earthquake was probably of the second order of intensity among destructive earthquakes. The Santiago earthquakes are chiefly interesting owing to the position of their centres along a well-known dislocation, nearly 1250 miles long, that skirts the southern coast of the east end of the island and forms the northern boundary of the Bartlett Trough, a depression that in one part reaches a depth of 3506 fathoms, or about four miles.

#### An Ancient Mexican Tomb

A VALUABLE addition to our knowledge of a little-known culture of ancient Mexico, that of the Mixtec, is promised by a recent find of which news has reached New York. In a dispatch from the *Times'* correspondent which appears in the issue of Jan. 20,

it is stated that information has been received that treasure in gold and precious stones "worth millions" has been discovered in a sealed tomb in the course of excavation, under the direction of Don Alfonso Caso, at Monte Alban, near Oaxaca. The bodies of ten Mixtec caciques were found buried under a heap of cups, urns, vases, and jars of jade, onyx, and crystal, together with personal ornaments and utensils of gold richly inlaid with turquoise. The skulls of the chiefs were encrusted with turquoise, and with them was a finely wrought mask of gold. The disorder of the funerary offerings suggests haste, and this might have been due to the fact that the interment lies in the country of the Zapotec, with whom the Mixtec, notwithstanding their probable affinity, were frequently at war.

THE richness of the funerary offerings found at Monte Alban is fully in accord with the account given by Balboa, an early writer on the inhabitants of Mexico, of an interment in a cave—the usual type of burial chamber among the Mixtec—situated at Chalcotonga, supposed to be the gate of Paradise, in which the dead were laid out in rich garments and a number of small idols of gold, stone, and wood were placed in niches in the walls of the cave. Primary interments such as the recent discovery are supposed to have been confined to persons of high rank, the lower orders being placed in the ground for a time and their bones then collected and placed in a vase for deposit in a cave. It is suggested that the date of the burial is the fifteenth or early sixteenth century. Notwithstanding the scanty details, it is evident that this is the most imposing discovery of relics of the pre-Columbian culture of Mexico yet made. Its interest is considerably enhanced by the fact that so little relating to the Mixtec, who may in part have been of pre-Aztec strain, had been discovered previously.

#### Electrical Measuring Instruments

A SPECIAL exhibition of electrical measuring instruments opens at the Science Museum, South Kensington, on Feb. 13, and will remain on view until the middle of May. The exhibition illustrates the evolution of electrical measuring instruments, from the discovery of the fundamental principles on which they are based, up to the present day, and is substantially the same as the exhibition arranged by the British Electrical and Allied Manufacturers' Association and shown on the occasion of the Faraday Centenary Exhibition at the Albert Hall in September last. With the view of interesting the non-technical public, a series of simple demonstration experiments has been arranged to illustrate the various fundamental principles and their application to electrical measurement. Demonstrations will be given daily, the apparatus in some cases being a replica of that used by the original discoverer of the principle. The exhibition, which comprises about 250 exhibits, includes many original instruments, such as Kelvin's reflecting galvanometer, a resistance coil used by Wheatstone, Joule's current balance, and the coil with which Maxwell determined the ohm. Among the interesting replicas are those of Ørsted's Compass, with which the magnetic effect

of an electric current was first demonstrated, Ampère's electrodynamic apparatus, the apparatus with which Ohm discovered 'Ohm's Law', and Sturgeon's electromagnetic engine, which was the first machine to embody a commutator.

#### Weights and Linear Measures

IN addition, a small exhibition of weighing and linear measuring instruments will be on view in the Main Entrance Hall of the Science Museum from February until May. The exhibition illustrates briefly, by objects and photographic transparencies, progress in metrology since early times. In the very limited space available, only one form of balance has been selected for illustration—the precision or equal-armed balance; similarly, only standard scales and micrometer development have been shown in the linear section. The exhibits include, however, the principal British Exchequer standard weights and linear measures from the time of Henry VII (1485), excepting, of course, the current national standards. This collection, hitherto in charge of the Standards Department of the Board of Trade, has now been transferred to the Science Museum.

#### World's Commercial Electricity Supply

THANKS to the activities of the World Power Conference, data in connexion with the supply of electricity throughout the world are now available. It appears that in 1930 the total capacity of the electric generators used was 114 million kilowatts and that the electric units (kw.h.) generated were 304,000 million. The electricity supply industry represents the largest public utility service in the world, and the capital invested in it almost equals the capital invested in railways. If we take as our unit a 1000 million kw.h., the total output of electricity in North America was 139, of which the United States generated 121, about two-fifths of the total world output. Germany comes next with an output of 29.4, Canada with 17.8, Great Britain with 17.2, Japan with 16.3, France with 15.9, and Italy with 10.8. Owing to the world-wide industrial depression, there is a distinct slowing down of the rate of development during this period as compared with the preceding year. This is mainly due to slackness in the industrialised countries of western Europe and North America. Statistics in connexion with the capacity of the dynamos installed raise the question of whether the generating equipment throughout the world has outrun the demands made on it. It is a little difficult to answer this question, but we think that when industry revives there will be an immediate demand for more electrical machines.

#### Northumbrian Coals

THE Fuel Research Board has just issued Paper No. 21 of the Physical and Chemical Survey of the National Coal Resources, being a report on the Yard Seam of Northumberland. The report is a very full one, and appears to be very carefully done. There is only one point to which attention may be directed. In places there is a narrow band of dirty coal at the top of the seam known locally as 'top brat', which the report states is "sometimes known as 'roof coal'".

or 'ramble'." From the wording of the report the reader might suppose that the term 'ramble' is confined to this particular coal, but as a matter of fact it is a generic term for any thin bed of shaly matter that comes down when the underlying coal is worked. Thus in the "Glossary of Terms used in the Coal Trade of Northumberland and Durham", by G. C. Greenwell, the first edition, published in 1849, defines ramble as "A thin stratum of shale, often found lying immediately above the seam of coal. It falls down, and, getting mixed with the coals, causes some trouble to the hewer, in getting it separated and cast back." Seeing that this brat, although described as dirty coal, is stated to have contained in one place as much as 69 per cent of ash, whereas one of the bands of shale contains only 46 per cent, it is obvious that this band might fairly come within Greenwell's definition. Perhaps the most interesting statement in the report is that the authors find "the coking properties of the seam to be weak, but not non-existent", seeing that Northumbrian coals are generally supposed to be non-coking, this statement is a very important one, and leads to the inference that the Yard Seam shales may be useful for blending with more strongly coking coals in order to produce a good metallurgical coke.

#### Cormorant Fishing in China

It is sometimes said that since the neolithic age man has made no progress in domesticating wild creatures, except for the improvements made in the breeds of animals domesticated at that time. But the domestication of the cormorant in China belongs to a much more recent period. The story has been worked out in detail by Berthold Laufer of the Field Museum of Natural History, Chicago (*Field Museum Publication* 300, Anthropological Series, vol. 18, 1931). The earliest mention of the use of trained cormorants for fishing refers to Japan and dates from about A.D. 607, when, presumably, such use was unknown in China. Yet the trained cormorants of Japan are scarcely more domesticated than the English cormorants which James I. delighted to watch, and for whom he appointed a 'master of the royal cormorants'. In China the birds are completely domesticated, being bred and reared in captivity, so that they become perfectly submissive to their masters, whose commands they understand, and whom they obey with the readiness and docility of a dog. Characteristic of their domestication is the appearance amongst them of colour varieties, particularly of albinistic and pied individuals. Their eggs are always hatched by domestic fowls and not by the cormorant mother, and the young are fed on special foods until the period of their training for fishing begins, and this lasts for seven or eight months.

#### Investigations of Isotopes in 1931

In the *Berichte der deutschen chemischen Gesellschaft* for January 1932 will be found a report by Prof. O. Hahn upon the progress made during the year 1931 in the investigation of isotopic forms of the elements. In a footnote it is explained that the German Chemical Society has arranged for the continuation of such reports upon this subject until

such time as an international commission shall have been set up for the purpose. The present report supplements the last biennial report, published in London nearly a year ago in the *Annual Reports of the Chemical Society*. After referring to the new determination by Mecke and Childs of the relative proportions in oxygen of its isotopes, and to the desirability of retaining oxygen for the present as the standard in estimating atomic weights in spite of its complex nature, the author of the report reviews the latest developments obtained by means of the mass-spectrograph and of band spectra. Two useful tables are appended, containing respectively a list of sixty-three elements, which have hitherto been examined, together with their isotopes, and a list of no fewer than thirty-six pairs of isobars of non-radioactive elements.

#### American Geophysical Union

THE *Transactions of the American Geophysical Union* (published by the National Research Council) at its twelfth annual meeting, on April 30–May 1, 1931, appeared in June. This promptness, due to the able organisation of the secretary, Dr. J. A. Fleming, and to the use of direct reproduction from typescript, much enhances the value of the report. From its 227 pages geophysicists elsewhere can obtain a rapid and comprehensive view of the large amount of work in this field now being done in the United States and, to a certain extent, in Canada and Mexico. The general assembly was mainly devoted to a symposium on time-signals, most of the work of the meeting is done in the seven sectional meetings. In seismology, the papers related chiefly to the development of new or improved instruments, in meteorology, to the work of the International Polar Year, in terrestrial magnetism and electricity, including radio work, the papers were very numerous and covered a wide range of subjects, in oceanography, the reports of many institutions on their past work were the main subject of discussion, hydrology forms a separate section, and had a long and varied programme, and there were a few papers on volcanology.

#### Apparatus for Absorption Spectrophotometry

MESSRS. Adam Hilger, Ltd., have published an interesting booklet dealing with the outfits they supply for absorption spectrophotometry in the visible and ultra-violet regions. The most important new instrument which is described is a form of ultra-violet spectrophotometer, working on the principle of the variation of the aperture of the beam, for which the name Spekker has been registered. This has been designed primarily for use with Hilger's medium quartz spectrographs, but may be attached to any similar instrument of sufficiently great aperture. Judging by the description of the instrument, and by a specimen set of absorption photographs for benzene in hexane, this should be both highly convenient to use and accurate in the results it yields. A photoelectric outfit is also described, although not very enthusiastically, the opinion being expressed that the use of a photoelectric cell in place of the eye or a photographic record diminishes the likelihood of a number of important sources of error being recognised, so that

there is a liability that copious and apparently highly accurate results may be amassed which are actually unreliable. Other devices listed include Bay and Steiner's hydrogen discharge tubes for providing continuous ultra-violet sources of light, and also a micrometer liquid cell for studying the absorption of thin layers of liquid.

#### Biology in Shakespeare

It would be indeed a difficult problem to conceive of any new point of view from which to study Shakespeare's works. In the *Scientific Monthly* for January, Prof Fraser-Harris has made a study of the world's greatest poet and dramatist from the point of view of biology, and though the topic is not a new one—there is a public garden in Manchester where nearly all the plants, wild and cultivated, mentioned in Shakespeare are grown, and references given—the method is new, in that Prof Fraser-Harris has aimed, not at giving a catalogue of plants and animals, but at considering a few allusions which are of distinctly physiological or psychological interest. For example, Prof Fraser-Harris claims four participating factors in sleep—chemical, vascular, sensory, and ideational, and Shakespeare recognises two of these in the famous soliloquy of the king in "Henry IV". Although Shakespeare was a contemporary of Harvey, there is no reference in his works to blood circulation, and though one might express surprise at this, Prof Fraser-Harris gives sufficient argument why Shakespeare was ignorant of the then new discovery. These are only two examples of how Shakespearean lines embody deep biological truths, many more, with the appropriate quotations and commentaries, are given by Prof Fraser-Harris in his interesting article.

#### Veterinary Research in South Africa

WE have received the seventeenth report of the Director (Prof P. J. du Toit) of Veterinary Services and Animal Industry, Onderstepoort, Pretoria (Union of S Africa Dep of Agriculture. The Government Printer, Pretoria, 1931. 10s each part). It is issued in two parts of about 425 pages each, is well produced and fully illustrated, and contains a mass of valuable material dealing with all branches of veterinary research and animal industry. Part 1 contains the parasitological matter, part 2 physiological, pathological, and industrial subjects and metabolism. Of general interest may be mentioned papers on a new and cheap method of preparing pure cystine from wool, and giving a high yield, by J. G. Louw, the good effects of sulphur on merino sheep in doses of 5 gm from once to six times weekly, the general condition of the animals, weight, and wool yield being strikingly improved, by D. G. Steyn, and the improved quality of bacon obtained by including barley meal in the pig's ration, by D. J. Schulte and C. A. Murray.

#### British Lenses

WE learn from Messrs Taylor, Taylor and Hobson, Ltd, that they have recently received a contract for no less than 350,000 lenses, totalling more than half a million glasses, for inexpensive hand cameras

Messrs Taylor, Taylor and Hobson produce costly Cooke lenses used in some of the world's leading observatories for stellar photography, and also highly corrected Cooke lenses of large aperture for the exacting requirements of the principal cinema studios throughout Britain and the United States. It is the high degree of precision demanded by these more expensive products that has enabled the firm to design and make machinery capable of producing inexpensive lenses in such quantities and in competition with such low Continental prices as those for which the above contract has been awarded.

#### Eskimo Settlement in Alaska

AN expedition of the University of Pennsylvania Museum, of which Miss Frederica de Laguna is the leader, working in Alaska during the past season, reports the discovery, according to Science Service, of a prehistoric Eskimo settlement at Cook's Inlet. This area is at present inhabited by Indians, and the settlement would appear to represent the most southerly extension of Eskimo culture known. Shell heaps on the shore, some of them ten to fourteen feet in height, have been investigated. Among the relics were a number of personal ornaments, including lip plugs, beads, an ivory pendant, a carved ivory head, and a nose-pin. The objects of domestic use included a lamp, a needle-case and needles, and an ivory catch for a box. One of the most interesting relics was a mirror of slate, of which the surface showed the reflection on being damped.

#### Esperanto in Scientific Literature

REFERRING to the recent correspondence in *NATURE* on Esperanto in scientific literature, Prof W. E. Collinson, professor of German and John Buchanan, lecturer in Esperanto in the University of Liverpool, has written stating that the fullest and most extensively documented account of such writings is Section 86 of Dr Eugen Wuster's "Internationale Sprachnormung in der Technik—besonders in der Elektrotechnik" (published with the support of the Akademie des Bauwesens, VDI-Verlag, Berlin, 1931). This work deals with the problem of the international standardisation of technical nomenclature in all its aspects, and shows the wide range of topics in which work has already appeared in Esperanto, namely, biochemistry, strength of materials, inorganic and organic chemistry, telephony and wireless, bacteriology, analytical geometry, etc.

#### Postponement of an International Congress

WE learn from the General Secretary, Prof. E. Moles, San Barnado 49, Madrid, that at a meeting of the Bureau of the International Union of Chemistry and the organising committee of the Ninth International Congress of Pure and Applied Chemistry held recently, it was decided to postpone the Congress indefinitely. The Congress was to have been at Madrid on April 3-10 this year, but it was felt that the present world-wide economic depression would limit seriously the usefulness of such a gathering. When conditions improve it is hoped to hold the Congress as originally arranged at Madrid.

## The Decline of Determinism \*

By SIR ARTHUR EDDINGTON, F R S

**D**ETERMINISM has faded out of theoretical physics. Its exit has been commented on in various ways. Some writers are incredulous, and cannot be persuaded that determinism has really been eliminated. Some think that it is only a domestic change in physics, having no reactions on general philosophic thought. Some imagine that it is a justification for miracles. Some decide cynically to wait and see if determinism fades in again.

The rejection of determinism is in no sense an abdication of scientific method, indeed it has increased the power and precision of the mathematical analysis of observed phenomena. On the other hand, I cannot agree with those who belittle the general philosophical significance of the change. The withdrawal of physical science from an attitude it has adopted consistently for more than two hundred years is not to be treated lightly, and it involves a reconsideration of our views with regard to one of the perplexing problems of our existence. In this address, I shall deal mainly with the physical universe, and say very little about mental determinism or freewill. That might well be left to those who are more accustomed to arguing about such questions, if only they could be awakened to the new situation which has arisen on the physical side. At present I can see little sign of such an awakening

### DEFINITIONS OF DETERMINISM

Let us first be sure that we agree as to what is meant by determinism. I quote three definitions or descriptions for your consideration. The first is by a mathematician (Laplace)

We ought then to regard the present state of the universe as the effect of its antecedent state and the cause of the state that is to follow. An intelligence, who for a given instant should be acquainted with all the forces by which Nature is animated and with the several positions of the entities composing it, if, further, his intellect were vast enough to submit those data to analysis, would include in one and the same formula the movements of the largest bodies in the universe

and those of the lightest atom. Nothing would be uncertain for him, the future as well as the past would be present to his eyes. The human mind in the perfection it has been able to give to astronomy affords a feeble outline of such an intelligence.

All its efforts in the search for truth tend to approximate without limit to the intelligence we have just imagined.

The second is by a philosopher (C. D. Broad)

'Determinism' is the name given to the following doctrine. Let  $S$  be any substance,  $\psi$  any characteristic, and  $t$  any moment. Suppose that  $S$  is in fact in the state  $\sigma$  with respect to  $\psi$  at  $t$ . Then the compound supposition that everything else in the world should have been exactly as it in fact was, and that  $S$  should have been in one of the other two alternative states with respect to  $\psi$  is an impossible one. [The three alternative states (of which  $\sigma$  is one) are to have the characteristic  $\psi$ , not to have it, and to be changing.]

The third is by a poet (Omar Khayyám)

With Earth's first Clay They did the Last Man knead,  
And there of the Last Harvest sow'd the Seed  
And the first Morning of Creation wrote  
What the Last Dawn of Reckoning shall read

I propose to take the poet's description as my standard. Perhaps this may seem an odd choice, but there is no doubt that his words express what is in our minds when we refer to determinism. The other two definitions need to be scrutinised suspiciously, we are afraid there may be a catch in them. In saying that the physical universe as now pictured is not a universe in which "the first morning of creation wrote what the last dawn of reckoning shall read", we make it clear that the abandonment of determinism is no technical quibble, but is to be understood in the most ordinary sense of the words.

It is important to notice that all three definitions introduce the time-element. Determinism postulates not merely causes but pre-existing causes. Determinism means predetermination. Hence in any argument about determinism the dating of the alleged causes is an important matter, we must challenge them to produce their birth certificates.

\* Presidential address to the Mathematical Association delivered on Jan 4

Ten years ago, practically every physicist of repute was, or believed himself to be, a determinist, at any rate so far as inorganic phenomena are concerned. He believed that he had come across a scheme of strictly causal law, and that it was the primary aim of science to fit as much of our experience as possible into such a scheme. The methods, definitions, and conceptions of physical science were so much bound up with this assumption of determinism that the limits (if any) of the scheme of causal law were looked upon as the ultimate limits of physical science.

To see the change that has occurred, we need only refer to a recent book which goes as deeply as anyone has yet penetrated into the fundamental structure of the physical universe, Dirac's "Quantum Mechanics". I do not know whether Dirac is a determinist or not, quite possibly he believes as firmly as ever in the existence of a scheme of strict causal law. But the significant thing is that in this book he has no occasion to refer to it. In the fullest account of what has yet been ascertained as to the way things work, causal law is not mentioned.

This is a deliberate change in the aim of theoretical physics. If the older physicist had been asked why he thought that progress consisted in fitting more and more phenomena into a deterministic scheme, his most effective reply would have been "What else is there to do?" A book such as Dirac's supplies the answer. For the new aim has been extraordinarily fruitful, and phenomena which had hitherto baffled exact mathematical treatment are now calculated and the predictions are verified by experiment. We shall see presently that indeterministic law is as useful a basis for practical predictions as deterministic law was. By all practical tests, progress along this new branch track must be recognised as a great advance in knowledge. No doubt some will say "Yes, but it is often necessary to make a detour in order to get round an obstacle. Presently we shall have passed the obstacle and be able to join the old road again." I should say rather that we are like explorers on whom at last it has dawned that there are other enterprises worth pursuing besides finding the North-West Passage, and we need not take too seriously the prophecy of the old mariners who regard these enterprises as a temporary diversion to be followed by a return to the 'true aim of geographical exploration'. But at the moment I am not concerned with prophecy and counter-prophecy, the important thing is to grasp the facts of the present situation.

## SECONDARY LAW

Let us first try to see how the new aim of physical science originated. We observe certain regularities in the course of Nature and formulate these as 'laws of Nature'. Laws may be stated positively or negatively, 'Thou shalt' or 'Thou shalt not'. For the present purpose it is most convenient to formulate them negatively. Consider the following two regularities which occur in our experience.

(a) We never come across equilateral triangles whose angles are unequal.

(b) We never come across 13 trumps in our hand at bridge.

In our ordinary outlook we explain these regularities in fundamentally different ways. We say that the first occurs because the contrary experience is *impossible*, the second occurs because the contrary experience is *too improbable*.

This distinction is entirely theoretical, there is nothing in the observations themselves to suggest to which type a particular regularity belongs. We recognise that 'impossible' and 'too improbable' can both give adequate explanation of any observed uniformity of experience, and the older theory rather haphazardly explained some uniformities one way and other uniformities the other way. In the new physics we make no such discrimination, the union obviously must be on the basis of (b), not (a). It can scarcely be supposed that there is a law of Nature which makes the holding of 13 trumps in a properly dealt hand impossible, but it *can* be supposed that our failure to find equilateral triangles with unequal angles is only because such triangles are too improbable.

We must, however, first consider the older view which distinguished type (a) as a special class of regularity. Accordingly, there were two types of natural law. The earth keeps revolving round the sun, because it is *impossible* it should run away. Heat flows from a hot body to a cold, because it is *too improbable* that it should flow the other way. I call the first type *primary* law, and the second type *secondary* law. The recognition of secondary law was the thin end of the wedge that ultimately cleft the deterministic scheme.

For practical purposes primary and secondary law exert equally strict control. The improbability referred to in secondary law is so enormous that failure even in an isolated case is not to be seriously contemplated. You would be utterly astounded if heat flowed from you to the fire so that you got chilled by standing in front of it, although such an occurrence is judged by physical theory to be not

impossible but improbable. Now it is axiomatic that in a deterministic scheme nothing is left to chance, a law which has the ghost of a chance of failure cannot form part of the scheme. So long as the aim of physics is to bring to light a deterministic scheme, the pursuit of secondary law is a blind alley since it leads only to probabilities. The determinist is not content with a law which prescribes that, given reasonable luck, the fire will warm me, he admits that that is the probable effect, but adds that somewhere at the base of physics there are other laws which prescribe just what the fire will do to me, luck or no luck.

To borrow an analogy from genetics, determinism is a *dominant character*. We can (and indeed must) have secondary indeterministic laws within any scheme of primary deterministic law—laws which tell us what is likely to happen but are overridden by the dominant laws which tell us what must happen. So determinism watched with equanimity the development of indeterministic law within itself. What matter? Deterministic law remains dominant. It was not foreseen that indeterministic law when fully grown might be able to stand by itself and supplant its dominant parent. There is a game called "Think of a number." After doubling, adding, and other calculations, there comes the direction "Take away the number you first thought of." We have reached that position in physics, and the time has come to take away the determinism we first thought of.

The growth of secondary law within the deterministic scheme was remarkable, and gradually sections of the subject formerly dealt with by primary law were transferred to it. There came a time when in some of the most progressive branches of physics secondary law was used exclusively. The physicist might continue to profess allegiance to primary law but he ceased to utilise it. Primary law was the gold to be kept stored in vaults, secondary law was the paper to be used for actual transactions. No one minded, it was taken for granted that the paper was backed by gold. At last came the crisis, and *physics went off the gold standard*. This happened very recently, and opinions are divided as to what the result will be. Prof. Einstein, I believe, fears disastrous inflation, and urges a return to sound currency—if we can discover it. But most theoretical physicists have begun to wonder why the now idle gold should have been credited with such magic properties. At any rate the thing has happened, and the immediate result has been a big advance in atomic physics.

We have seen that indeterministic or secondary

law accounts for regularities of experience, so that it can be used for predicting the future as satisfactorily as primary law. The predictions and regularities refer to average behaviour of the vast number of particles concerned in most of our observations. When we deal with fewer particles the indeterminacy begins to be appreciable, and prediction becomes more of a gamble, until finally the behaviour of a single atom or electron has a very large measure of indeterminacy. Although some courses may be more probable than others, backing an electron to do anything is in general as uncertain as backing a horse.

It is commonly objected that our uncertainty as to what the electron will do in the future is due not to indeterminism but to ignorance. It is asserted that some character exists in the electron or its surroundings which decides its future, only physicists have not yet learned how to detect it. You will see later how I deal with this suggestion. But I would here point out that if the physicist is to take any part in the wider discussion on determinism as affecting the significance of our lives and the responsibility of our decisions, he must do so on the basis of what he has discovered, not on the basis of what it is conjectured he might discover. His first step should be to make clear that he no longer holds the position, occupied for so long, of chief advocate for determinism, and that he is *unaware* of any deterministic law in the physical universe. He steps aside and leaves it to others—philosophers, psychologists, theologians—to come forward and show, if they can, that they have found indications of determinism in some other way\*. If no one comes forward, the hypothesis of determinism presumably drops, and the question whether physics is actually antagonistic to it scarcely arises. It is no use looking for an opposer until there is a proposer in the field.

#### INFERENTIAL KNOWLEDGE

It is now necessary to examine rather closely the nature of our knowledge of the physical universe.

All our knowledge of physical objects is by inference. We have no means of getting into direct contact with them, but they emit and scatter light waves, and they are the source of pressures transmitted through adjacent material. They are like broadcasting stations that send out signals which

\* With the view of learning what might be said from the philosophical side against the abandonment of determinism, I took part in a symposium of the Aristotelian Society and Mind Association in July 1931. Indeterminists were strongly represented, but unfortunately there were no determinists in the symposium, and apparently none in the audience which discussed it. I can scarcely suppose that determinist philosophers are extinct, but it may be left to their colleagues to deal with them.

we can receive. At one stage of the transmission the signals pass along nerves within our bodies. Ultimately visual, tactual, and other sensations are provoked in the mind. It is from these remote effects that we have to argue back to the properties of the physical object at the far end of the chain of transmission. The image which arises in the mind is not the physical object, though it is a source of information about the physical object, to confuse the mental object with the physical object is to confuse the clue with the criminal. Life would be impossible if there were no kind of correspondence between the external world and the picture of it in our minds, and natural selection (reinforced where necessary by the selective activity of the Lunacy Commissioners) has seen to it that the correspondence is sufficient for practical needs. But we cannot rely on the correspondence, and in physics we do not accept any detail of the picture unless it is confirmed by more exact methods of inference.

The external world of physics is thus a universe populated with *inferences*. The inferences differ in degree and not in kind. Familiar objects which I handle are just as much inferential as a remote star which I infer from a faint image on a photographic plate, or an 'undiscovered' planet inferred from irregularities in the motion of Uranus. It is sometimes asserted that electrons are essentially more hypothetical than stars. There is no ground for such a distinction. By an instrument called a Geiger counter, electrons may be counted one by one as an observer counts one by one the stars in the sky. In each case the actual counting depends on a remote indication of the physical object. Erroneous properties may be attributed to the electron by fallacious or insufficiently grounded inference, so that we may have a totally wrong impression of what it is we are counting, but the same is equally true of the stars.

In the universe of inferences, past, present, and future appear simultaneously, and it requires scientific analysis to sort them out. By a certain rule of inference, namely, the law of gravitation, we infer the present or past existence of a dark companion to a star, by an application of the same rule of inference we infer the existence on Aug. 11, 1999, of a configuration of the sun, earth, and moon, which corresponds to a total eclipse of the sun. The shadow of the moon on Cornwall in 1999 is already in the universe of inference. It will not change its status when the year 1999 arrives and the eclipse is observed, we shall merely substitute one method of inferring the shadow for another. The shadow will always be an inference. I am

speaking of the object or condition in the external world which is called a shadow, our perception of darkness is not the physical shadow, but is one of the possible clues from which its existence can be inferred.

Of particular importance to the problem of determinism are our inferences about the past. Strictly speaking, our direct inferences from sight, sound, touch, all relate to a time slightly antecedent, but often the lag is more considerable. Suppose that we wish to discover the constitution of a certain salt. We put it in a test tube, apply certain reagents, and ultimately reach the conclusion that it *was* silver nitrate. It is no longer silver nitrate after our treatment of it. This is an example of retrospective inference: the property which we infer is not that of 'being X' but of 'having been X'.

We noted at the outset that in considering determinism the alleged causes must be challenged to produce their birth certificates so that we may know whether they really were pre-existing. Retrospective inference is particularly dangerous in this connexion because it involves antedating a certificate. The experiment above mentioned certifies the chemical constitution of a substance, but the date we write on the certificate is earlier than the date of the experiment. The antedating is often quite legitimate, but that makes the practice all the more dangerous, it lulls us into a feeling of security.

#### RETROSPECTIVE CHARACTERS

To show how retrospective inference might be abused, suppose that there were no way of learning the chemical constitution of a substance without destroying it. By hypothesis a chemist would never know until after his experiment what substance he had been handling, so that the result of every experiment he performed would be entirely unforeseen. Must he then admit that the laws of chemistry are chaotic? A man of resource would override such a trifling obstacle. If he were discreet enough never to say beforehand what his experiment was going to demonstrate, he might give edifying lectures on the uniformity of Nature. He puts a lighted match in a cylinder of gas, and the gas burns. "There you see that hydrogen is inflammable." Or the match goes out. "That proves that nitrogen does not support combustion." Or it burns more brightly. "Evidently oxygen feeds combustion." "How do you know it was oxygen?" "By retrospective inference from the fact that the match burned more brightly." And so the experimenter passes from cylinder to cylinder, the

match sometimes behaves one way and sometimes another, thereby beautifully demonstrating the uniformity of Nature and the determinism of chemical law<sup>1</sup>. It would be unkind to ask how the match must behave in order to indicate indeterminism.

If by retrospective inference we infer characters at an earlier date, and then say that those characters invariably produce at a future date the manifestation from which we inferred them, we are working in a circle. The connexion is not causation but definition, and we are not prophets but tautologists. We must not mix up the genuine achievements of scientific prediction with this kind of charlatanry, or the observed uniformities of Nature with those so easily invented by our imaginary lecturer. It is easily seen that to avoid vicious circles we must abolish purely retrospective characteristics—those which are never found as existing but always as having existed. If they do not manifest themselves until the moment that they cease to exist, they can never be used for prediction except by those who prophesy after the event.

Chemical constitution is not a retrospective character, though it is often inferred retrospectively. The fact that silver nitrate can be bought and sold shows that there is a property of *being* silver nitrate as well as of *having been* silver nitrate. Apart from special methods of determining the constitution or properties of a substance without destroying it, there is one general method widely applicable. We divide the specimen into two parts, analyse one part (destroying it if necessary), and show that its constitution *has been* X, then it is usually a fair inference that the constitution of the other part *is* X. It is sometimes argued that in this way a character inferable retrospectively must always be also inferable contemporaneously, if that were true, it would remove all danger of using retrospective inference to invent fictitious characters as causes of the events observed. Actually the danger arises just at the point where the method of sampling breaks down, namely, when we are concerned with characteristics supposed to distinguish one individual atom from another atom of the same substance, for the individual atom cannot be divided into two samples, one to analyse and one to preserve. Let us take an example.

It is known that potassium consists of two kinds of atoms, one kind being radioactive and the other inert. Let us call the two kinds  $K\alpha$  and  $K\beta$ . If we observe that a particular atom bursts in the radioactive manner, we shall infer that it was a  $K\alpha$  atom. Can we say that the explosion was pre-

determined by the fact that it was a  $K\alpha$  and not a  $K\beta$  atom? On the information stated there is no justification at all,  $K\alpha$  is merely an antedated label which we attach to the atom when we see that it has burst. We can always do that, however undetermined the event may be which occasions the label. Actually, however, there is more information which shows that the burst is not undetermined. Potassium is found to consist of two isotopes of atomic weights 39 and 41, and it is believed that 41 is the radioactive kind, 39 being inert. It is possible to separate the two isotopes and to pick out atoms known to be  $K^{41}$ . Thus,  $K^{41}$  is a contemporaneous character, and can legitimately predetermine the subsequent radioactive outburst, it replaces  $K\alpha$  which was a retrospective character.

So much for the fact of outburst, now consider the time of outburst. Nothing is known as to the time when a particular  $K^{41}$  atom will burst except that it will probably be within the next thousand million years. If, however, we observe that it bursts at a time  $t$ , we can ascribe to the atom the retrospective character  $K^t$ , meaning that it had (all along) the property that it was going to burst at time  $t$ . Now, according to modern physics, the character  $K^t$  is not manifested in any way—is not even represented in our mathematical description of the atom—until the time  $t$  when the burst occurs and the character  $K^t$ , having finished its job, disappears. In these circumstances  $K^t$  is not a pre-determining cause. Our retrospective labels and characters add nothing to the plain observational fact that the burst occurred without warning at the moment  $t$ , they are merely devices for ringing a change on the tenses.

The time of break-up of a radioactive atom is an example of extreme indeterminism; but it must be understood that, according to current theory, all future events are indeterminate in greater or lesser degree, and differ only in the margin of uncertainty. When the uncertainty is below our limits of measurement, the event is looked upon as practically determinate, determinacy in this sense is relative to the refinement of our measurements. A being accustomed to time on the cosmic scale, who was not particular to a few hundred million years or so, might regard the time of break-up of the radioactive atom as practically determinate. There is one unified system of secondary law throughout physics and a continuous gradation from phenomena predictable with overwhelming probability to phenomena which are altogether indeterminate.

## CRITICISM OF INDETERMINISM

In saying that there is no contemporaneous characteristic of the radioactive atom determining the date at which it is going to break up, we mean that in the picture of the atom as drawn in present-day physics no such characteristic appears, the atom which will break up in 1960 and the atom which will break up in the year 150,000 are drawn precisely alike. But, it will be said, surely that only means that the characteristic is one which physics has not yet discovered, in due time it will be found and inserted in the picture either of the atom or its environment. If such indeterminacy were exceptional, that would be the natural conclusion, and we should have no objection to accepting such an explanation as a likely way out of a difficulty. But the radioactive atom was not brought forward as a difficulty, it was brought forward as a favourable illustration of that which applies in greater or lesser degree to all kinds of phenomena. There is a difference between explaining away an exception and explaining away a rule.

The persistent critic continues: "You are evading the point. I contend that there are characteristics unknown to you which completely predetermine not only the time of break-up of the radioactive atom but also all physical phenomena. How do you know there are not? You are not omniscient."

The curious thing is that the determinist who takes this line is under the illusion that he is adopting a more modest attitude in regard to our scientific knowledge than the indeterminist. The indeterminist is accused of claiming omniscience. I will not make quite the same countercharge against the determinist, but surely it is only a man who thinks himself *nearly* omniscient who would have the audacity to start enumerating all the things which (it occurs to him) might exist without his knowing it. I am so far from omniscient that my list would contain innumerable entries. If it is any satisfaction to the critic, my list does include deterministic characters—along with Martian irrigation works, ectoplasm, etc.—as things which might exist unknown to me.

It must be realised that determinism is a positive assertion about the behaviour of the universe. It is not sufficient for the determinist to claim that there is no fatal objection to his assertion, he must produce some reason for making it. I do not say he must prove it, for in science we are ready to believe things on evidence falling short of strict proof. If no reason for asserting it can be given,

it collapses as an idle speculation. It is astonishing that even scientific writers on determinism advocate it without thinking it necessary to say anything in its favour, merely pointing out that the new physical theories do not actually disprove determinism. If that really represents the status of determinism, no reputable scientific journal would waste space over it. Conjectures put forward on slender evidence are the curse of science, a conjecture for which there is no evidence at all is an outrage. So far as the physical universe is concerned, determinism appears to explain nothing for in the modern books which go farthest into the theory of the phenomena no use is made of it.

Indeterminism is not a positive assertion. I am an indeterminist in the same way that I am an anti-moon-is-made-of-green-cheese-ist. That does not mean that I especially identify myself with the doctrine that the moon is *not* made of green cheese. Whether or not the green cheese lunar theory can be reconciled with modern astronomy is scarcely worth inquiring, the main point is that green-cheesism, like determinism, is a conjecture that we have no reason for entertaining. Undisprovable hypotheses of that kind can be invented *ad lib*.

## PRINCIPLE OF UNCERTAINTY

The mathematical treatment of an indeterminate universe does not differ much in form from the older treatment designed for a determinate universe. The equations of wave mechanics used in the new theory are not different in principle from those of hydrodynamics. The fact is that, since an algebraic symbol can be used to represent either a known or an unknown quantity, we can symbolise a definitely predetermined future or an unknown future in the same way. The difference is that whereas in the older formulæ every symbol was theoretically determinable by observation, in the present theory there occur symbols the values of which are not assignable by observation.

Hence, if we use the equations to predict, say, the future velocity of an electron, the result will be an expression containing, besides known symbols, a number of undeterminable symbols. The latter make the prediction indeterminate. (I am not here trying to prove or explain the indeterminacy of the future, I am only stating how we adapt our mathematical technique to deal with an indeterminate future.) The indeterminate symbols can often (or perhaps always) be expressed as unknown phase-angles. When a large number of phase-angles are involved, we may assume in averaging that they are uniformly distributed from  $0^\circ$  to

360°, and so obtain predictions which could only fail if there has been an unlikely coincidence of phase-angles. That is the secret of all our successful prophecies, the unknowns are not eliminated by determinate equations but by averaging.

There is a very remarkable relation between the determined and the undetermined symbols, which is known as Heisenberg's Principle of Uncertainty. The symbols are paired together, every determined symbol having an undetermined symbol as partner. I think that this regularity makes it clear that the occurrence of undetermined symbols in the mathematical theory is not a blemish, it gives a special kind of symmetry to the whole picture. The theoretical limitation on our power of predicting the future is seen to be systematic, and it cannot be confused with other casual limitations due to our lack of skill.

Let us consider an isolated system. It is part of a universe of inference, and all that can be embodied in it must be capable of being inferred from the influence which it broadcasts over its surroundings. Whenever we state the properties of a body in terms of physical quantities, we are imparting knowledge as to the response of various external indicators to its presence and nothing more. A knowledge of the response of all kinds of objects would determine completely its relation to its environment, leaving only its unget-at-able inner nature, which is outside the scope of physics. Thus, if the system is really isolated so that it has no interaction with its surroundings, it has no properties belonging to physics, but only an inner nature which is beyond physics. So we must modify the conditions a little. Let it for a moment have some interaction with the world exterior to it, the interaction starts a train of influences which may reach an observer, he can from this one signal draw an inference about the system, that is, fix the value of one of the symbols describing the system or fix one equation for determining their values. To determine more symbols there must be further interactions, one for each new value fixed. It might seem that in time we could fix all the symbols in this way, so that there would be no undetermined symbols in the description of the system. But it must be remembered that the interaction which disturbs the external world by a signal also reacts on the system.

There is thus a double consequence, the interaction starts a signal through the external world informing us that the value of a certain symbol  $p$  in the system is  $p_1$ , and at the same time it alters to an indeterminable extent the value of another

symbol  $q$  in the system. If we had learned from former signals that the value of  $q$  was  $q_1$ , our knowledge will cease to apply, and we must start again to find the new value of  $q$ . Presently there may be another interaction which tells us that  $q$  is now  $q_2$ , but the same interaction knocks out the value  $p_1$  and we no longer know  $p$ . It is of the utmost importance for prediction that a paired symbol and not the inferred symbol is upset by the interaction. If the signal taught us that at the moment of interaction  $p$  was  $p_1$ , but that  $p$  had been upset by the interaction and the value no longer held good, we should never have anything but retrospective knowledge—like the chemistry lecturer to whom I referred above. Actually we can have contemporaneous knowledge of the values of half the symbols, but never more than half. We are like the comedian picking up parcels who, each time he picks up one, drops another.

There are various possible transformations of the symbols and the condition can be expressed in another way. Instead of two paired symbols, one wholly known and the other wholly unknown, we can take two symbols each of which is known with some uncertainty, then the rule is that the product of the two uncertainties is fixed. Any interaction which reduces the uncertainty of determination of one increases the uncertainty of the other. For example, the position and velocity of an electron are paired in this way. We can fix the position with a probable error of 0.001 mm and the velocity with a probable error of about 1 km per sec, or we can fix the position to 0.0001 mm and the velocity to 10 km per sec, and so on. We divide the uncertainty how we like, but we cannot get rid of it. If current theory is right, this is not a question of lack of skill or a perverse delight of Nature in tantalising us, for the uncertainty is actually embodied in the theoretical picture of the electron, so that if we describe something as having exact position and velocity we cannot be describing an electron.

If we divide the uncertainty in position and velocity at time  $t_1$  in the most favourable way, we find that the predicted position of the electron one second later (at time  $t_2$ ) is uncertain to about five centimetres. That represents the extent to which the future position is not predetermined by anything existing one second earlier. If the position at time  $t_2$  always remained uncertain to this extent, there would be no failure of determinism, for the thing we had failed to predict (exact position at time  $t_2$ ) would be meaningless. But *when the second has elapsed* we can measure the position of the electron to 0.001 mm or even more closely, as

already stated This accurate position is not predetermined, we have to wait until the time arrives and then measure it It may be recalled that the new knowledge is acquired at a price Along with our rough knowledge of position (to 5 cm) we had a fair knowledge of the velocity, but when we acquire more accurate knowledge of the position, the velocity goes back into extreme uncertainty

We might spend a long while admiring the detailed working of this cunning arrangement by which we are prevented from finding out more than we ought to know But I do not think we should look on these as Nature's devices to prevent us from seeing too far into the future. They are the devices of the mathematician who has to protect himself from making impossible predictions It commonly happens that when we ask silly questions, mathematical theory does not directly refuse to answer but gives a non-committal answer like  $\frac{0}{0}$ , out of which we cannot wring any definite meaning Similarly, when we ask where the electron will be to-morrow, mathematical theory does not give the straightforward answer, "It is impossible to say, because it is not yet decided", because that is beyond the resources of an algebraic vocabulary It gives us an ordinary formula of  $x$ 's and  $y$ 's, but makes sure that we cannot possibly find out what the formula means—until to-morrow

#### MENTAL INDETERMINISM

I have, perhaps fortunately, left myself no time to discuss the effect of indeterminacy in the physical universe on our general outlook I will content myself with stating in summary form the points which seem to arise

(1) If the whole physical universe is deterministic, mental decisions (or at least *effective* mental decisions) must also be predetermined For if it is predetermined in the physical world (to which your body belongs) that there will be a pipe between your lips on Jan 1, the result of your mental struggle on Dec 31 as to whether you will give up smoking in the New Year is evidently predetermined The new physics thus opens the door to indeterminacy of mental phenomena, whereas the old deterministic physics bolted and barred it completely

(2) The door is opened slightly, but apparently the opening is not wide enough, for according to analogy with inorganic physical systems, we should expect the indeterminacy of human movements to be quantitatively insignificant In some way we must transfer to human movements the

wide indeterminacy characteristic of atoms, instead of the almost negligible indeterminacy manifested by inorganic systems of comparable scale I think this difficulty is not insuperable, but it must not be underrated

(3) Although we may be uncertain as to the intermediate steps, we can scarcely doubt what is the final answer If the atom has indeterminacy, surely the human mind will have an equal indeterminacy, for we can scarcely accept a theory which makes out the mind to be more mechanistic than the atom

(4) Is the human will really more free if its decisions are swayed by new factors born from moment to moment than if they are the outcome solely of heredity, training, and other predetermining causes? On such questions as these we have nothing new to say Argument will no doubt continue 'about it and about' But it seems to me that there is a far more important aspect of indeterminacy. It makes it possible that the mind is not utterly deceived as to the mode in which its decisions are reached On the deterministic theory of the physical world, my hand in writing this address is guided in a predetermined course according to the equations of mathematical physics; my mind is unessential—a busybody who invents an irrelevant story about a scientific argument as an explanation of what my hand is doing—an explanation which can only be described as a downright lie If it is true that the mind is so utterly deceived in the story it weaves round our human actions, I do not see where we are to obtain our confidence in the story it tells of the physical universe

Physics is becoming difficult to understand First relativity theory, then quantum theory, then wave mechanics have transformed the universe, making it seem ever more fantastic to our minds Perhaps the end is not yet But there is another side to this transformation Naïve realism, materialism, the mechanistic hypothesis were simple, but I think that it was only by closing our eyes to the essential nature of experience, relating as it does to the reactions of a conscious being, that they could be made to seem credible. These revolutions of scientific thought are clearing up the deeper contradictions between life and theoretical knowledge, and the latest phase with its release from determinism marks a great step onwards I will even venture to say that in the present theory of the physical universe we have at last reached something which a reasonable man might almost believe.

### Announcements

THE annual Sir John Rhys Memorial Lecture of the British Academy will be delivered on Feb. 17 by Prof. H. J. Fleure, professor of geography in the University of Manchester, who will take as his subject "Archæology and Folk-Tradition".

THE ninety-first annual general meeting of the Chemical Society will be held in Glasgow on March 18, under the presidency of Prof. G. G. Henderson, regius professor of chemistry in the University of Glasgow, who will take as the subject for his address "The Publication of Chemical Literature". This will be the first official visit of the Society to Scotland.

THE Right Hon. Lord Plender; Mr. Bertram S. Thomas, Arabian explorer and orientalist; and the Rev. A. T. P. Williams, headmaster of Winchester College, have been elected members of the Athenæum under the provisions of Rule II. of the Club, which empowers the annual election by the committee of a certain number of persons of distinguished eminence in science, literature, the arts, or for public services.

THE Langley Prize, which is usually awarded every three years for the best paper submitted by officers of the West African Medical Service—whether on the active or retired list—has been awarded by the London School of Hygiene and Tropical Medicine in equal shares for Dr. E. C. Smith's paper "A Dermatological Atlas of Nigeria" and for Dr. Hope Gill's paper "Diagnostic Methods in Human Trypanosomiasis".

THE following appointments in the Colonial Agricultural Service have recently been made by the Secretary of State for the Colonies: Mr. G. E. Bodkin, Government entomologist, Palestine, to be director of agriculture, Mauritius; Mr. A. S. Thomas, economic botanist, Gold Coast, to be assistant botanist, Uganda; Mr. J. E. P. Booth, to be agricultural officer, Kenya; Mr. R. E. T. Hobbs, to be agricultural officer, Kenya; Mr. W. T. Dalgarno, to be agricultural instructor, Bahamas; Mr. J. C. Eyre, to be district agricultural officer, Tanganyika Territory.

IN view of the present situation, and the recent appointment of Dr. C. P. Blacker as general secretary of the Eugenics Society, the salaried appointment of Mrs. C. B. S. Hodson will terminate next August. Mrs. Hodson is to continue to work in close association with the Society as a member of the council, and so secure the continuation of the eugenic work already begun in different parts of Great Britain. This arrangement leaves unaffected Mrs. Hodson's position as honorary administrative secretary to the International Federation of Eugenic Organizations, and she retains her place on the Committee for Legalising Eugenic Sterilization.

OWING to the closing of Chillingham Castle, Northumberland, efforts are being made to keep together the famous herd of wild cattle which is believed to have roamed in the castle enclosure since the thirteenth century. It is announced in the *Times* of Feb. 8 that the Zoological Society of London has

undertaken to contribute £100 a year for seven years if a lease at £500 a year for that period is granted to three trustees nominated by the Society. The remainder of the £500 a year is to be provided by public subscription. The trustees are Lord Grey of Fallodon, Mr. Hugh S. Gladstone, and Sir Peter Chalmers Mitchell. A public appeal will shortly be made.

WE have received List No. 23, January 1932, of Eastman Organic Chemicals, from the Eastman Kodak Co., Rochester, New York. This contains the names of a large number of special chemicals already available, and also several additions, the specification of which occupies six pages of the catalogue. The prices of all the chemicals are given, and a valuable feature of the list is the inclusion of the physical constants of nearly all the chemicals.

MR. C. R. S. MANDERS suggests in a letter to the Editor that a magnetic field might produce a marked change in the specific inductive capacity of substance. The suggestion is fairly obvious, but no references are given to work upon the subject; and as Mr. Manders gives no address, we are unable to return his letter.

APPLICATIONS are invited for the following appointments, on or before the dates mentioned:—An assistant secretary of the University of Birmingham—The Secretary, University, Birmingham (Feb. 15). A senior assistant hydrometric engineer in the Civil Engineering Department of the Electricity Supply Board of the Irish Free State—The Secretary, Electricity Supply Board, 60-62 Upper Mount Street, Dublin (Feb. 17). A senior assistant in the library of the University College of Hull—The Registrar, University College, Hull (Feb. 19). An assistant master, mainly for chemistry and physics, at the Acton Technical College—The Principal, Technical College, Acton (Feb. 20). A junior lecturer in the Department of Pathology, University of Liverpool—The Professor of Pathology, University, Liverpool (Feb. 21). A lecturer in engineering at the Wigan and District Mining and Technical College—The Principal, Wigan and District Mining and Technical College, Wigan (Feb. 22). A head of the Department of Industrial and Fine Art, Loughborough College—The Registrar, Loughborough College, Loughborough (Feb. 26). A principal of the Westminster Technical Institute—The Education Officer (T.1), County Hall, Westminster Bridge, S.E.1 (Feb. 29). A lecturer in experimental pathology and assistant director of cancer research in the University of Leeds—The Registrar, University, Leeds (March 1). A professor of anatomy in the University of Lucknow—The Registrar, Lucknow University, Lucknow, India (March 30). A part-time lecturer in Sinhalese at the School of Oriental Studies—The Secretary, School of Oriental Studies, Finsbury Circus, E.C.2 (April 20). A lecturer in English in the University of Hong Kong—The Secretary, Universities Bureau of the British Empire, 88A Gower Street, W.C.1 (April 30). A professor of agricultural botany in the University of Reading—The Registrar, University, Reading.

## Artificial Production of Fast Protons

A HIGH potential laboratory has been developed at the Cavendish Laboratory for the study of the properties of high speed positive ions. The potential from a high voltage transformer is rectified and multiplied four times by a special arrangement of rectifiers and condensers, giving a working steady potential of 800 kilovolts. Currents of the order of a milliampere may be obtained at a potential constant to 1.2 per cent.

Protons from a discharge in hydrogen are directed down the axis of two glass cylinders 14 in. in diameter and 36 in. long, and accelerated by the steady potentials of the rectifier. They are then passed into an experimental chamber at atmospheric pressure through a mica window having a stopping power of about 1 mm. air equivalent. Luminescence of the air can easily be observed.

The ranges of the protons in air and hydrogen have been measured using a fluorescent screen as a detector. The range in air at S.T.P. of a proton having a velocity of  $10^9$  cm./sec. is found to be 8.2 mm., whilst the corresponding range for hydrogen is 3.2 cm. The observed ranges support the general conclusions of Blackett on the relative ranges of protons and  $\alpha$ -particles, although the absolute values of the ranges are lower for both gases. The ranges and stopping power will be measured more accurately by an ionisation method.

The maximum energy of the protons produced up to the present has been 710 kilovolts with a velocity of  $1.16 \times 10^9$  cm./sec. and a corresponding range in air of 13.5 mm. at S.T.P. We do not anticipate any difficulty in working up to 800 kilovolts with our present apparatus.

Structure of Normal and Mutant Eyes in *Gammarus chevreuxi*

Numerous mutant types of eye have been found in *Gammarus chevreuxi* by Sexton, and their genetic behaviour analysed by her and various other workers.<sup>1</sup> We have now examined the structure of some of these, and find certain surprising results. The normal or wild type eye is of the usual structure,<sup>2</sup> with hypodermis, crystalline cones, rhabdomes, and reticular cells. Prolongations of the reticular cells surround the rhabdomes and the base of the cones, and are the seat of both the red and black pigments of the eye. In addition, between the rhabdomes and cones are to be seen interstitial cells, which contain the interommatidial white pigment characteristic of so many gammarids.

The albino mutant is a simple recessive (*ccW*, as against *CW* for wild type, where *C-c* is the gene controlling the appearance of red and black pigments). It lacks both red and black pigment; the eye is irregular and entirely white. Sections (Fig. 1) show that the crystalline cones are present, but irregularly spheroidal and situated at various levels instead of conical and at a constant level; the bulk of the eye consists of interstitial cells, much hypertrophied in size and possibly increased in number. There is a total absence of retinula. No connexion exists between eye and brain, and the optic ganglion also appears to be absent. In most cases the eye in section is of a fairly regular flattened cake-like shape, but sometimes irregular prolongations of the interstitial tissue extend somewhat into the interior of the head.

The colourless eye is the product of two recessive genes (*ccww* in genetic constitution, where *W-w* is the gene controlling the appearance of white pigment). In sections, colourless eyes are in general similar to albino eyes. But the crystalline cones are usually increased in number, and may be irregularly fused with each other in a very peculiar way, while the interstitial tissue may be somewhat reduced, and may show signs of degeneration (abnormally staining nuclei, and crystalline inclusions in the cells).

In both albino and colourless eyes a peculiar large-celled spongy tissue pervades much of the head; the origin and nature of this has not yet been satisfactorily determined. It might possibly be a modification of the connective tissue found surrounding

FIG. 1.—Sections of normal and mutant eyes of *Gammarus chevreuxi*. A, normal eye; B, albino eye; C, colourless eye. *b*, brain; *c*, crystalline cones; *h*, hypodermis, with overlying cuticle; *i*, interstitial tissue; *o.g.*, optic ganglion; *r*, reticular tissue; *rh*, position of rhabdomes (and interstitial cells in normal); *s*, spongy tissue (in mutants).

the brain in the wild type, or may be derived from the abnormal development of reticular and optic ganglion rudiments.

The main differentiation of the eye occurs from about two days before hatching (at 23° C) to a little after hatching. Sections taken of embryos during this period show that from the outset the cells which should give rise to reticular tissue are very much reduced in number in albinos; the first origin of interstitial tissue appears to take place at the usual time.

It is hoped to make a further analysis of the earlier developmental processes leading to the mutant types. Meanwhile the work has already explained one genetic puzzle. In most known cases of mendelising colour-characters, single mutations affect the chemical processes leading to the formation of one particular kind of pigment. But the *cc* mutation of *Gammarus* affects two wholly different kinds of pigment, a red lipochrome and a black melanin. This is now seen to be due to the fact that both these pigments are normally present only in the reticular cells, and that the primary effect of the *c* gene is to prevent the development of these cells.

As the albino and colourless eyes are so defective in structure, and have no connexion with the brain, they would be expected to be functionless. This appears to be the case. Normal *Gammarus* are slightly negatively phototropic; albino specimens appear not to be. Owing to the constant restless swimming of this species only statistical results can be obtained. A long tube containing twenty specimens was illuminated from one end and the number of specimens in the half nearer the light counted at regular intervals. In a series of experiments the average percentage of animals in the half nearer the source of light was 35 per cent for wild type, but 45 per cent for albinos. Further, from experiments in which the tube is reversed at regular intervals, it seems that there is a true directive effect of light in the wild type, but that the distribution of the albinos is a matter of chance; for the number of specimens in the half nearer the light is *always* less than 50 per cent in the wild type, while in the albinos it alternates regularly between less than 50 per cent and more than 50 per cent. It is very difficult to make good sections from the adult eyes. We have to thank Dr H. Eltringham, who has special experience with arthropods, for kindly cutting the adult specimens here described and illustrated.

### Photochemical Reaction between Hydrogen and Chlorine in the Presence of Oxygen

It has been generally assumed that the hydrogen chloride produced when a mixture of hydrogen and chlorine is illuminated has no effect on the velocity of reaction. If, however, the magnitudes of the Draper effects are considered for two reaction mixtures which do not differ in hydrogen, chlorine, and oxygen concentrations, but only in the circumstance that one (a) contains no hydrogen chloride, and the other (b) an amount of hydrogen chloride equal, say, to that of the concentration of chlorine, then the magnitude of the Draper effect in (a) can be observed to fall off very rapidly on illumination, while that of (b) shows no such rapid initial fall but is always smaller than the initial value in the case of (a).

Indications of a rapid initial fall in reaction velocity in mixtures containing initially no hydrogen chloride can indeed be recognised in the 'velocity coefficients' given by several workers, for example, by Bodenstein and Dux.<sup>1</sup>

Experiment has shown that the presence of hydrogen chloride (in the reaction vessel) does markedly inhibit the reaction. The apparatus employed was essentially that described by Griffiths and Norrish.<sup>2</sup> With the plane-faced quartz and glass reaction vessels here used, chlorine at 50 mm pressure absorbed about fifty per cent of the incident light of wave-length 365  $\mu$ . By calibrating the light absorption against concentration, concentrations of chlorine in this region could be determined from the absorption with an accuracy greater than 0.5 mm. This was the method of measurement of hydrogen chloride formation, quantum efficiency figures in general being repeatable with an accuracy within 5 per cent.

Some experimental figures for two wave-lengths are given graphically in Fig. 1, which refers always to an average pressure of chlorine and hydrogen equal

FIG. 1.

to 44 mm each, and a pressure of oxygen equal to 50 mm. The two curves are directly comparable, and the efficiency of the formation per absorbed quantum is always less for light of wave-length 406  $\mu$  than for light of 365  $\mu$ .

Experiments with low oxygen concentration (<10 mm) gave similar results. Our results to date are closely reproduced by the following expression for the quantum efficiency of hydrogen chloride formation

$$\gamma_{\text{HCl}} = \frac{k_1}{(\text{O}_2)([\text{HCl}] + k_2)}$$

This formula has been established so far over a range of pressure of oxygen of from 10 mm to 350 mm, and for a ten-fold variation in light intensity, it will, however, be somewhat amplified when we have completed the study of the separate variation of the hydrogen and chlorine concentrations, which up to the present have been kept constant.

That the inhibiting action of hydrogen chloride as it accumulates is quite specific and unconnected with any 'inert gas effect' is evidenced by the fact that the addition of nitrogen has no action on the course of the reaction. The results were always repeatable to within 5 per cent, whether the hydrogen chloride was added to the system, or allowed to accumulate.

as the result of reaction, and no irregularities were ever observed such as would indicate the presence of chance inhibitors

A series of experiments was also carried out with phosphorus pentoxide in the reaction vessel. Provided the phosphorus pentoxide was dry, no absorption of hydrogen chloride occurred, and the pressure change, measured by a Bourdon gauge, indicated the rate of formation of water. The quantum efficiency of water formation rose from a low value ( $<0.2$ ) to a value not greater than 1 as the hydrogen chloride concentration was increased from zero to 400 mm (oxygen, 50 mm, average chlorine and average hydrogen, 44 mm). The chains of the hydrogen chloride reaction must therefore be broken by the hydrogen chloride and oxygen, acting jointly, possibly in a ternary collision of  $H$ ,  $O_2$ , and  $HCl$ , with water as one of the products.

The inhibiting action of hydrogen chloride puts a new complexion on the kinetics of the hydrogen-chlorine reaction. Neglect of this factor is responsible for the diverse quantum efficiencies recorded by different observers. When it is taken into consideration in systems containing oxygen, the quantum efficiency is surprisingly repeatable. In cases where a water actinometer is used, the hydrogen chloride is absorbed as it is formed, and in any given system there will be a certain arbitrary equilibrium concentration of hydrogen chloride (dependent on the light intensity and dimensions of the vessel) which will control the speed of the action. In this connexion the results of Allmand and Beesley,<sup>3</sup> who report a maximum in the apparent quantum efficiency as the wave-length of the active light is decreased from  $436\text{ }\mu$  to  $365\text{ }\mu$ , must be reconsidered. It seems likely that with the high intensity light of these wave-lengths, greater equilibrium concentrations of hydrogen chloride were established in the actinometer than with the less intense violet ( $406\text{ }\mu$ ) light obtainable from the mercury vapour lamp. The quantum efficiency would therefore show an apparent maximum in the violet. We have shown above, however, that when the concentration of hydrogen chloride is also taken into account, the quantum efficiency increases between  $406\text{ }\mu$  and  $365\text{ }\mu$ .

#### Co-ordination of Hydrogen in Associated Liquids

SIMONS and Bouknight<sup>1</sup> have described measurements of the density and surface tension of hydrogen fluoride at various temperatures, but in their discussion, although they calculate the Eotvos constant, they do not give any value of the parachor.

Using their results and the measurements of the vapour density made by Simons and Hildebrand in 1924, the parachor can be evaluated, and the figures show that it increases from 34.2 at  $-80^\circ$  to 35.8 at  $19.5^\circ$ .

This result is an interesting addition to those quoted by Sidgwick and Bayliss<sup>2</sup> in support of their ideas on the co-ordination of hydrogen in associated liquids. The 'theoretical' parachor for hydrogen fluoride is 42.8, so that the actual value shows a defect nearly equal to the 7.2 which should characterise a liquid associating to double molecules, moreover, the defect

decreases steadily with rise of temperature, as was to have been anticipated, suggesting a decrease in the extent of the association.

It is noteworthy that if, on the other hand, single electron bonds are assumed in order to avoid the expansion of the electronic group of the hydrogen atom implied above, then a smaller degree of association would be required to account for the defect observed—a smaller one than perhaps seems likely from other considerations.

#### Oxygen and Everest

THERE are one or two statements in Sir Leonard Hill's letter, and that of Dr. Greene, in *NATURE* of Jan. 16, which I think require comment and correction.

It would surely be difficult to instance a more cogent demonstration of the possibilities of high altitude acclimatisation than that provided by the recent Bavarian expedition to Kangchenjunga. The climbing party were able by reason of slow upward progress, consequent upon the extreme difficulties of the lower part of their route, to attain such a degree of acclimatisation that at approximately 26,000 ft they were ascending, in deep snow, at the remarkable rate of 650 ft per hour. Sir Leonard altogether fails to appreciate what this performance means, and the fact that the party were carrying very heavy loads makes it all the more remarkable. Sir Leonard elsewhere emphasises that one (though only one) of the party had heart-trouble. In the circumstances, was it not surprising that more of the party had not heart- and other organic troubles? We find, however, that their later strenuous activities in the region, during their return, suggest neither deterioration nor organic degeneration as a result of their amazing efforts on the mountain.

Sir Leonard is incorrect in his statement that the climbers on the last Everest expedition, who persevered at 28,000 ft, all came to grief.<sup>1</sup> As mentioned in my last letter, neither Norton nor Somervell were in the pink of condition when they commenced their climb, and Norton, who persisted to about 28,126 ft, turned back because of the lateness of the hour and his anxiety to regain Somervell before nightfall. He had by no means come to grief, and could have persevered higher, in spite of eye trouble consequent upon having removed his snow-goggles earlier in the day. The strength of re-radiated light at these altitudes, even from bare rock surfaces, had been sufficient to affect his unprotected eyes. Moreover, none of the 1924 Everest party can be said to have suffered, like the animals of the experiment, degenerate organic change from their sojourn at high altitudes. On leaving Tibet they were mostly in excellent condition, and no one has suffered any after-effects.

It may well be that the cats, rats, and mice, etc., of Dr. Campbell's experiment showed no interest in continuing to live at the low oxygen partial pressures to which they were subjected, in spite of being brought gradually to such pressures. But the latter process quite obviously did not constitute acclimatisation, nor was it at all likely to do so considering the complete inactivity meanwhile of the subjects of the experiment.

Whatever analogies, however, on a physical basis may be drawn, such experiments on animals entirely leave out of account the psychological factor so germane to all man's higher activities. The will

to climb higher, the exhilaration of possible success, apart from the accompanying stimulating effects of environment in this case. These psychological factors have their physical reactions, which are quite certainly of a beneficial character.

As we have said before, however, though acclimatisation to the highest altitudes should be aimed at, and has, we believe, already been demonstrated to 27,000 ft in 1924, we recommended at that time that light oxygen equipment be available in case of need on another Everest attempt. Whether such apparatus be used by the actual climbing party on emergency, or merely for experimental purposes on an attached 'physiological squad', it would be desirable to have it as light in weight as possible. If the metallurgist could be prevailed upon to devise an even lighter alloy for gas cylinders than the 'Vibrac' steel used in 1924, it might so materially reduce the total load and bulk of the apparatus as to warrant belief in its possible practicability, either on the final portion of the ascent or for use in high camps by unacclimatised persons, or even during spells of intense cold under the latter conditions some persons have reported experiencing benefit from breathing oxygen—but this is only another symptom of inadequate acclimatisation.

Liquid oxygen apparatus has been considered, but has been ruled out as quite impracticable for mountain use.

Finally, Sir Leonard queries whether the failure of the hill-peoples of the Himalaya to go above 18,000 ft during the summer months may not be on account of realisation of the physiological injuriousness of doing so. The alternative, of the upper limit of pastures, must surely here be the deciding factor, since, so far as I am aware, no grazing beyond that sufficient for the burhel and other mountain sheep exists above 18,000 ft in any part of the Himalaya. Most plants, even of the simple alpine types, cease at 18,000-19,000 ft, although on Everest and Kangchenjunga hardy species of *Arenaria* and *Delphinium* have been found as high as 20,400 ft and 20,600 ft respectively but these are exceptions.

#### Atomic Weight of Fluorine

We find ourselves in complete agreement with Prof Moles's remarks<sup>1</sup> on the values which can be obtained for the atomic weight of fluorine from the limiting densities of silicon fluoride. It appears to us, however, that when two theoretically calculated compressibility coefficients applied to the same data lead to values of the atomic weight of fluorine of 19.09 and 18.995 respectively, little significance can be attached to either of these values.

We would like to point out that the work of McAdam and Smith<sup>2</sup> on the ratio of sodium chloride to sodium fluoride gave an atomic weight of 19.015 when their weighings were not corrected to a vacuum. These results have been corrected to a vacuum by Smith and Haagen (*Carnegie Institution Report*, No 267, p 47), who thus find the value 19.009 (not 19.019 as stated by Prof Moles).

In our original letter we did not bring forward the work of Smith and Haagen (*Carnegie Institution Report*, No 267) on the ratio of borax to various other salts, as these lead to an atomic weight of boron differing considerably from the accepted value. If, however, we assume that the cross ratios from their mean values give trustworthy data for finding the atomic

weight of fluorine, we obtain the following results (taking Na = 22.997, C = 12.005, N = 14.009, S = 32.068)

| Cross ratio |                                 | At Wt Fluorine |
|-------------|---------------------------------|----------------|
| NaF         | NaCl                            | 19.001         |
| 2 NaF       | Na <sub>2</sub> SO <sub>4</sub> | 19.003         |
| NaF         | NaNO <sub>3</sub>               | 19.004         |
| 2 NaF       | Na <sub>2</sub> CO <sub>3</sub> | 19.008         |
|             |                                 | Average 19.004 |

Smith and Haagen themselves give an average value  $F = 19.005$ . Combining Smith and Haagen's results with those of McAdam and Smith, it seems likely that, as we suggested in our original communication, the stoichiometric atomic weight of fluorine lies in the neighbourhood of 19.01 rather than 19.00.

Prof Moles has suggested that our preliminary higher value for the atomic weight (19.01) is due to the gas, which was made by Collie's method, consisting of a constant boiling mixture of methyl fluoride and 2 per cent of methane. This could not explain the divergence, since if the presence of such an amount of methane were assumed, the pure methyl fluoride would give an atomic weight of the order of 19.4.

We have read Gonzalez's paper<sup>3</sup> on the preparation of methyl fluoride by Collie's method. We consider that his results afford no evidence that the purified methyl fluoride he prepared in this way consisted of a constant boiling mixture of methyl fluoride and methane. He did not detect the presence of methane in his purified gas, but merely inferred the existence of a constant boiling mixture, since the vapour pressure and the density of his gas disagreed with those of methyl fluoride made by the methyl sulphate and the silver fluoride-methyl iodide methods. We did not use these latter methods in our work, as we considered it unlikely that pure methyl fluoride could be obtained in these ways. By diffusion, Gonzalez failed to show the presence of an impurity in the purified methyl fluoride made by Collie's method. On general grounds, it is unlikely that methyl fluoride and methane would form a constant boiling mixture. It appears to us that the experimental evidence points to the fact that Gonzalez obtained pure methyl fluoride, whilst the other methods lead to an impure product. This view is supported by the fact that the gases made by Moles and Batuecas by the methyl sulphate and the silver fluoride-methyl iodide methods show differences in mean density amounting to 0.006 in the atomic weight of fluorine.

In conclusion, we may say that we do not wish to stress unduly from our own preliminary experiments a value of  $F = 19.01$  rather than  $F = 19.00$  for the atomic weight of fluorine. The chemical evidence at present available, however, appears to point to the higher value. The question can only be settled by further experiment.

#### Structure and Development of Temperature Inversions in the Atmosphere

MESSRS Mal, Basu, and Desai have discussed recently<sup>1</sup> the subject of temperature inversions with dry air above them. Their forthcoming publication, in which the effects of turbulence and radiation are discussed quantitatively, will be welcomed by meteorologists. It is, however, scarcely correct to

state that the present view implies that the discontinuity of temperature develops before that of humidity. Some years ago I discussed the prevailing ideas on this subject<sup>2</sup> (including a paragraph drawn up in collaboration with the late M. A. Giblett), and the view taken was rather that the discontinuities of humidity and of temperature develop simultaneously under the influence of a number of factors. The main emphasis was placed on the adiabatic warming of slowly descending air, with its greater effect on dry than on cloudy air, and on turbulence up to a limit which becomes gradually lower and more sharply defined. The importance of radiation in increasing existing discontinuities was mentioned, though no doubt it ought to have been stressed more strongly.

Adiabatic warming gives a simple explanation of both the warmth and dryness above the inversions, and, moreover, these inversions are found when descending air is to be inferred from divergence in the horizontal air motion. They are by no means always present above horizontal cloud-sheets. In the particular circumstances mentioned by Messrs. Mal, Basu, and Desai, namely, in the region between a retreating cyclone and an advancing anticyclone, the observed change leading up to the inversion is normally a rise of temperature above the inversion level rather than a fall below it.

If we consider inversions in all conditions, we find that a rise of temperature above and a fall below are about equally important on the average, but it must be remembered that the air is normally in motion. In the rare cases when the air is stagnant the observed changes of upper air temperature and humidity are small. It is essential to distinguish between changes at one place and changes in a given mass of air. In the case of an inversion it is sometimes necessary to follow the air masses above and below it on separate tracks, but this is by no means always so, since many anticyclonic inversions are associated with no appreciable discontinuity of wind. (For theoretical reasons this means that they are horizontal.)

At present the aerological data are insufficient for any direct quantitative investigation, and similar remarks apply to the development of clouds from haze layers. In England most dry inversions are found above strato-cumulus clouds formed initially over the sea, and the most frequent level of the inversions is at about 4000 ft in winter and 6000 ft in summer. Over land in winter there is little tendency for the formation of strato-cumulus clouds, but only of fog or very low stratus.

#### Melde's String vibrated by Rotating Pulley

IN view of the fact that in the violin the bow is often held inclined to the string, it was presumed that the bow produced both a longitudinal and a transverse force at the point of contact during bowing. The vibration of the violin string would, therefore, be the superposition of the vibrations due to these two separate forces.

To test this, a Melde's string was excited by passing it over a pulley and making the pulley rotate. This gave a constant longitudinal force acting upon the string. The vibration was excited quite easily. A length of 2 metres vibrated with the fundamental having an amplitude of about 3.5 cm ( $2a=7$ ), the first harmonic had an amplitude of 2 cm nearly, the second 1 cm nearly. In the actual experiment

the horizontal rotating axle of the viscosity apparatus (method of concentric cylinders) was used for the pulley. The string was passed round this axle and tied to two screws nearly 4 cm apart. Sometimes the top string vibrated and sometimes the lower, as the tension in the two strings was adjusted. This showed that the effect was not spurious and was not due to any transverse motion of the axle. The tension away from the fixed end generally gave the lower frequencies, the tension towards the fixed end the higher ones.

The string was next passed over a smooth pulley rotating at right angles to the length of the string. The middle pulley of the step-down gear of the Callendar's apparatus for the determination of  $J$  was used for the purpose. The fixed end of the string was placed as close to the pulley as possible. The vibration could be seen to have a frequency absolutely distinct from that of the pulley, being much higher than it. The amplitudes worked up compared with the amplitudes for the longitudinal mode of excitation.

The production of continuous motion by vibration is well known. The reader may take the experiments here described as the converse of experiments discussed by Taber Jones<sup>1</sup> and by Morton and McKinstry<sup>2</sup>.

#### Cytology of the Mycetozoa

IN reply to Miss Lister's recent communication,<sup>1</sup> I should like to raise the following points.

1. The statement concerning the spore-wall, p. 106 of my paper,<sup>1</sup> is meant to apply particularly to *Didymium nigripes* var. *xanthopus* and not generally to other members of the Mycetozoa. The complete statement is as follows: "The spore of *Didymium nigripes* is rounded to oval in shape and approximately 10 to 12  $\mu$  in diameter. The spore membrane is comparatively thin, consisting of a single dark-coloured layer, 2  $\mu$  in width, and not of two layers as stated in Lister's Monograph."

2. I do not wish to disregard the monospore cultures made by other investigators, but merely to point out that I have had difficulty myself. Indeed, I am of the opinion that there is a much greater possibility of obtaining satisfactory monospore cultures in *Didymium nigripes* var. *xanthopus* than there was in *Reticularia* (p. 126). On p. 99 I refer to Cayley's monospore cultures and express the hope that I shall be able to repeat my endeavour to isolate single spores, using her method.

3. On p. 129 I refer to the discovery of flagellate fusion in *Didymium difforme* by Cayley, but I do feel that such a conclusion should be supported by investigation of nuclear detail in stained preparations.

4. I have already apologised to Miss Cayley for having misunderstood her views concerning the connexion of sex segregation with meiosis, and am sorry that I was so much influenced by her diagram, which she admits is rather misleading.

I should like to thank Miss Lister very much for the great interest she has shown in my work, and I trust that the above will make quite clear the points she raises.

## Research Items

Excavations at Fara—A preliminary report by Dr Erich Schmidt on a short season's work at Fara appears in the *Museum Journal* (Philadelphia), vol 22, 3-4. Fara lies north-west of Ur. The surface of the mound was much disturbed by the Koldewey Expedition of 1902-3. Work was confined to a few test plots at points of medium height, three to eight metres above plain level. The original ground surface level was attained in one group of twin plots. Three strata or periods were distinguished. Fara III is a settlement of the time of the third dynasty of Ur (2400-2300 B.C.) which was known as Shuruppak. As the remains of Fara II begin immediately below the surface of the mound, the only evidence for the existence of this settlement in the plots investigated is that yielded by a well-built circular construction of brick which proved to be a granary of the second period filled in by debris, including a number of human skeletons, of the third period. One of two cuneiform tablets speaks of 'the year when Gmíl-Sin became king'. The most striking finds were a number of pottery figurines or 'plaques', valuable especially for the style of dress and the insignia of royalty or deity. Fara II, 'the Early Sumerian', found immediately below the surface and extending down to a sterile stratum, saw the climax of the life of the mound, when it was large and wealthy. The finds included a large number of archaic inventory tablets. Lumps and fragments of copper were found at all depths. Below the sterile layer is Fara I, 'the Painted Pottery period', comparable to Jemdet Nasr culture, with suggestions of, but as yet no very definite clue to, the earlier al'Ubaid period. Fara I has as yet provided no written records. Fara, like Ur and Kish, thus supplies evidence of an inundation, but the occurrence of pottery and seals of Fara II in association with the Jemdet Nasr levels is interpreted to mean that while the Jemdet Nasr and 'early Sumerian' cultures were independent, they yet lived side by side during the infiltration of the Sumerian and until Jemdet Nasr died out.

Inheritance of Intelligence—In a recent study of the relation between intelligence and inheritance, by Miss E. M. Lawrence (*British Jour. Psychol.*, Monograph Supplements, 16), the Stanford-Binet tests and, in certain cases, tests devised by the National Institute of Industrial Psychology, were applied to several groups of children of school age. One group is the inmates of a home for illegitimate children separated from their parents at an average age of six months, another group consists of the children in an institution which admits children who need a home for any cause, two groups were from poor law homes, and the fifth from a London elementary school. Various statistical comparisons are then made between the I.Q. of the children and the social class of the parents. One conclusion reached is that even if the child has never lived with its parents, it is likely to have a slightly higher intelligence if its parents came from the upper classes than if they came from labouring people, although there are numerous exceptions both ways. The association of intelligence with class is greater for children who remained longer in their own homes, but the intelligence of children removed from bad surroundings apparently does not improve in a good environment. All the figures show a big drop in intelligence level with age, which means that the tests for successive years are too steeply graded. Illegitimate children are not significantly more or less intelligent than others. Various other

relationships are brought out in this paper, which concludes with a bibliography of the recent literature on this subject.

Physiology of Rheumatism—Ll. J. Llewellyn and A. Bassett Jones suggest that 'rheumatism' is the result of the body's failure to adapt itself to its physical environment, or atmospheric changes in their widest sense (*Brit. Jour. Physical Medicine*, vol 6, p 181, 1931). It is well known that rheumatic subjects are abnormally sensitive to changes in the weather, moreover, rheumatism is much more prevalent in the temperate zone with its variable climate than in the frigid or torrid zones. It is probable that the sympathetic nervous system and the endocrine glands are involved in the response of the body to changes in its environment, and that some deficiency in the response of these systems is the ultimate cause of the body's failure of adaptation. Thus the response to changes in temperature largely depends on the proper functioning of the sympathetic nervous system, owing to its control of the sweat glands and the distribution of blood in the body, a high external temperature results in sweating and dilatation of the skin blood vessels, by which means the surface of the body is cooled. The skin must play an important part in this adaptation, since it is the receptor for many of the stimuli impinging upon the body, as well as being the chief site of heat loss. Now, the skin contains unusual amounts of the amino acids, tyrosine and cystine (presumably in protein combination), tyrosine is closely related to adrenaline and thyroxine, the active principles of the medulla of the suprarenal and of the thyroid glands respectively, both of which play important parts in heat production in the body, tyrosine and cystine are also constituents of insulin. The authors suggest, therefore, that ultra-violet rays, for example, can mobilise tyrosine from the skin (a process comparable to the conversion of ergosterol to vitamin D), and thus affect the supply of thyroxine and adrenaline to the tissues in general, and that rheumatism may be the result of an inadequate supply of tyrosine and cystine in the skin together with deficient exposure to sunlight.

Protective Coloration of Birds' Eggs—In the recent number of the *Journal of the Bombay Natural History Society* (October, p 250), Mr E. C. Stuart Baker describes a case discovered by Mr J. Stuart of localised protective coloration in the eggs of a ground-nesting bird, the yellow-wattled lapwing (*Lobophanes malabarica*), which, on a belt of brick-red laterite soil stretching along the Malabar coast into Travancore, lays remarkably assimilated red eggs, but earthy coloured ones on the black soil areas around. The conclusion is drawn that, as the birds increased on the black soil, some were forced to colonise the red belt, and here only such eggs as exhibited a reddish tinge could escape vermin, so that in the course of generations the red protective type was evolved. In view of the well-known proneness of eggs to mutation, a simpler explanation would seem to be that the birds originally bred indiscriminately over the whole area, that some red egg-laying mutants were always present, and that these only could maintain themselves on the red soil belt.

Yagé, a South American Drug Plant—Extensive collections of Indian drug plants made by Mr Guillermo Klug, of Iquitos, Peru, in the Putumayo region of south-eastern Columbia, include three species of *Banisteriopsis* (family Malpighiaceae). These plants are known by the Indians under the general name of 'yagé', and they are boiled until

a syrup is produced. To this is added leaves and young shoots of a particular species of the genus, and to this is attributed the 'blush aureole' seen by the Indians in the state of anæsthesia into which they fall after drinking the liquor. The liquor appears to excite the cerebral centres of vision, and it is stated that, as a result, their sensibility is so developed that after drinking yagé a person is capable of "seeing objects in the midst of the most complete obscurity." Mr Klug was also informed that this drink was a very effective cure for malaria. Specimens from Mr Klug's collections have now reached the United States National Museum, and Mr C. V. Morton has described a new species (*J. Wash. Acad. Sci.*, vol 21, No 20, 1931), with notes on the action of the drug supplied by Mr Klug.

**Composite Nature of Potato Virus Diseases**—Dr Kenneth Smith, in his recent paper "On the Composite Nature of Certain Potato Virus Diseases of the Mosaic Group as revealed by the Use of Plant Indicators and Selective Methods of Transmission" (*Proc. Roy. Soc. B*, 109, pp 251-267, see also *NATURE*, 127, 702, May 9, 1931), has brought good evidence to show that the mosaic, crinkle, and streak diseases of potatoes are each caused by more than one virus. The aphid *Myzus persicae*, Sulz., will not carry any of the diseases mentioned as a whole, but only one or more of the component viruses. Plant indicators, such as tobacco, are also used, for when a composite mosaic is inoculated on them they show different symptoms if more than one virus is concerned. Plants of *Datura Stramonium* and *Petunia* are susceptible to one of the viruses, but not to the others. It is also found that the component viruses have different incubation periods and different rates of transmission within the host plant. This also can be used to separate them. Two viruses, named provisionally *x* and *y*, have been isolated from a symptomless 'streak'-carrying potato (Up-to-Date), and *y* seems to be a widespread component of potato virus diseases. The work here reported should go far towards standardising our knowledge of the diseases which cause the so-called potato 'degeneration'.

**Reactions of Horizons in Tropical Soils**—This subject is discussed in relation to the soils of Nyasaland by A. J. W. Hornby in a letter in *NATURE* for Jan 9, p 58. It is also one of the many interesting points dealt with by D. S. Gracie in a pamphlet on "A Preliminary Survey of Some of the Soils in Kenya" (*Bull.* 1, 1930, Dept. Agri., Kenya). These surveys were carried out on a profile basis to a depth of five feet, for it was realised—and the importance of the point clearly demonstrated in the course of the work—that although the surface layers are the more intimately connected with the crop, yet subsoil conditions may necessitate considerable modification of conclusions derived from a study of the surface layer alone. Instances are cited where the acidity increased continuously with depth, but no indication of these undesirable conditions was shown in the surface soil, the agricultural value of which, however, was seriously affected. Soil colour is also intimately associated with soil fertility, for removal and redepositions of iron, which are closely correlated with the degree of acidity and the amount of humus that is lost, are accompanied by changes in the colour of the soil. Another factor of fundamental importance is the nature and amount of organic matter present. This is found to be, under natural conditions, a function of the exchangeable calcium, the degree of acidity, and the climate, for acidity or lack of available calcium arises from lack of suitable organic material. That climatic conditions also play a part is well brought out by a comparison of the humus content of

soils (similar as regards exchangeable calcium and pH value) from different altitudes. Throughout the survey the practical aspect, that is, the value of the soil to the agriculturist, has been kept in the foreground, and a section of the bulletin is devoted to a discussion on the improvement and maintenance of the fertility of soils of different derivations.

**Algal Origin of Petroleum**—An important paper to those interested in the biochemical aspects of petroleum genesis was communicated to the Institution of Petroleum Technologists on Jan 12 by Mr J. E. Hackford. As he rightly points out, the origin of oil from decomposition of marine vegetation is a generally accepted thesis in many cases, but the precise mechanism of the chemical actions involved has lacked detailed investigation. In practically all accounts of the organic origin of petroleum, the geochemical processes contributing to its formation are stated with almost convincing logicity, but the mist becomes nearly impenetrable when information is sought as to the manner in which organic debris gradually changes into the oily globule and the precise chemical circumstances involved. The author claims to have established the formation of oil from algae by processes similar to those obtaining in Nature, the presence of decomposition products of algae in both naturally occurring oils as obtained from wells and also from seepage oils and bituminous deposits, the reconversion of oils into materials closely resembling, sometimes identical with, the constituents and decomposition products of algae, the formation of oils from sugars, and the reconversion of oils into bodies resembling bitumens which upon hydrolysis yield sugars. The work as a whole supports the algal theory of the origin of some classes of petroleum, and goes further than this: that oil and bitumen are in the main produced from the sugars resultant upon the hydrolysis of algae. From this, the author concludes that the vegetal theory of origin should be renamed "The Carbohydrate Theory of the Origin of Oil." This is one of the most interesting, if not provocative, papers presented to oil technologists for some time past, and the conception of the fucose-petroleum cycle, as it is called, constitutes a welcome advance in this difficult domain of biochemistry.

**Nature of the Carbon Dioxide Molecule**—It has been suggested from the way in which the specific heat of carbon dioxide alters with temperature that it exists in two forms, one straight and the other slightly bent, but conflicting results for the dielectric constant have made it impossible to decide from this if the bent form, which should have a permanent dipole moment, does actually exist. T. L. Ibbs and A. C. R. Wakeman have recently described a series of experiments on the thermal diffusion of carbon dioxide in gas mixtures, and on its viscosity, which seem to decide the point at issue (*Proc. Roy. Soc.*, Jan). With both phenomena it has been found that sharp changes occur in the curves connecting the numerical measure of the effect with the temperature, at about 140°C. In the case of diffusion, the transition temperature is 146° for a hydrogen mixture and 144° for a nitrogen mixture. This change is described by saying that the carbon dioxide molecule is 'hard' above 145° and 'soft' below this temperature. In the case of the viscosity, the change occurred at 140°, in excellent agreement with the results of other experimenters. From a discussion of these and other data it is suggested that the 'soft' and 'hard' modifications have, respectively, the straight and bent structural formulæ.

**Hydrides of Boron**—The preparation of the hydrides of boron by the usual method of the interaction

between an acid in aqueous solution and an alloy of boron gives very poor yields and is long and tedious. Schlesinger and Burg have described (*J. Amer. Chem. Soc.*, Dec 1931) a method for the preparation of diborane,  $B_2H_6$ , which consists in the reduction of gaseous boron trichloride by hydrogen in an electric arc discharge at low pressure. Boron, various non-volatile hydrides and large yields of an unstable spontaneously inflammable substance, considered from its reactions to be  $B_2H_5Cl$ , are also formed. The last-named compound, however, on warming decomposes and gives a further quantity of diborane  $6B_2H_5Cl = 5B_2H_6 + 2BCl_3$ . When diborane containing a small quantity of hydrogen chloride is heated at  $120^\circ$ - $130^\circ$  a considerable proportion is converted into the more stable pentaboron hydride  $B_5H_9$ .

**Aromatic Nitroso-Compounds in Solution**—The apparent molecular weights of nitrosobenzene and a number of its derivatives were determined in dilute solutions, mostly in benzene, by Bamberger and co-workers, and the results seemed to indicate that the state was unimolecular. Hammick has shown that these results are ambiguous, and has described new experiments with co-workers on nitrosobenzene and several substituted products (*J. Chem. Soc.*, Dec 1931). The results show that nitrosobenzene itself and its meta- and para-derivatives are associated in dilute solution. In the case of mono- and di-ortho-substituents a steric effect was detected. The degree of association of nitrosobenzene itself is quite small, about 2.4 per cent, but in some of the derivatives large associations were found, such as 38.2 per cent for o-nitronitrosobenzene and 77.3 per cent for nitroso-mesitylene. In the di-ortho-substituted derivatives

there is enormously enhanced stability of the bimolecular form. The first step in association in the case of nitrosobenzene is thought to be dipole association, although it is considered unlikely that the bimolecular forms of nitroso-compounds are simply dipole aggregates, and the dipole aggregate is thought to pass into an oxyazoxy-structure.

**A Compound of Nitrobenzene and Sulphuric Acid**—A compound,  $C_6H_5NO_2 \cdot H_2SO_4$ , separates on cooling an equimolecular mixture of the two components, the melting point,  $11.6^\circ$ , being higher than that of either component. Masson has published (*J. Chem. Soc.*, Dec. 1931) a complete freezing-point diagram for the two substances, which shows a well-defined maximum corresponding with the equimolecular compound and two eutectics, so that probably this is the only compound formed. The compound forms colourless needles at low temperatures, but at room temperature is an oily liquid which is surprisingly sluggish towards water and does not liberate much heat when decomposed by it. In sulphuric acid it forms solutions which conduct better than the acid alone, so that the compound is regarded as an electrolyte  $(C_6H_5 \cdot NO_2 \cdot H)^+ (HSO_4)^-$ , the hydrogen ion or proton being co-ordinated with one of the oxygen atoms of the nitro-group. The attachment of the positive hydrogen ion to the nitro-group should promote meta-substitution in the same way as happens with an arylammonium ion. The stability of the compound suggests, indeed, that in the dinitration of nitrobenzene it may well be the positive nitrobenzene-hydrogen ion, rather than the neutral nitrobenzene molecule, which is the main organic reagent and thus the source of the preponderating meta-derivative.

### Astronomical Topics

**Reinmuth's New Object**—Dr Kahrstedt has published elements of this object in *Rech. Inst. Circ.* 534, as follows:

|          |                      |
|----------|----------------------|
| T        | 1933 Oct 28 2854 U T |
| $\omega$ | $96^\circ 34' 0''$   |
| $\Omega$ | $45 \ 46 \ 21$       |
| $i$      | $31 \ 14 \ 21$       |
| $e$      | $0.1624184$          |
| $\log q$ | $0.6578513$          |
| Period   | $12.65425$ years     |

The orbit is still very uncertain, the arc being short. The object appears to be of the same type as comet Schwassmann-Wachmann (1), but with a somewhat smaller orbit that comes inside that of Jupiter at perihelion. The orbit makes a near approach to that of Jupiter at the descending node. The above circular gives an ephemeris for February and March, but as the comet is fainter than mag 15, it is not given here.

*Rech. Inst. Circ.* No 540, dated Jan 30, states that Prof M. Wolf has changed his opinion about the object, and no longer considers that it is nebulous; it may, therefore, be a minor planet, not a comet, but even in this case it deserves attention, as its orbit appears to be of an unusual type.

**The Light Variation of Cepheids**—*Meddelande* of Lund Observatory, Series I, No 128, contains a study by Dr K. Lundmark of the correlations between period and magnitude and between period and amplitude of light-change in the Cepheid variables. He includes in his study the stars in the Magellanic Clouds, the nearest two spiral nebulae, the globular clusters, also galactic Cepheids. Graphs are given for the Cepheids in all these different regions, they agree in showing a close correlation between magnitude and logarithm of period, when the maximum

magnitude is used, there is greater departure from a linear graph when the minimum magnitudes are used. There are also clearly recognisable correlations between amplitude and magnitude, but the graphs are more curved. It is noted that Dr Hertzsprung found little trace of this last correlation in the stars near Eta Carinae, but probably the stars that he was discussing were at very different distances.

Dr Lundmark uses his adopted curves to obtain new estimates of the distances in light-years of the various objects, of course, they do not differ much from those already published. He finds for the Greater Cloud 95,000 light-years, for the Lesser one 112,000 light-years, for NGC 6822 690,000 light-years, for the Andromeda nebula 840,000 light-years, for Messier 33 860,000 light-years, the distance between the last two objects would be 224,000 light-years.

*Rocznik Astronomiczny*, Cracow Observatory.—No 10 of this annual publication, edited by T. Banachiewicz, contains the ephemerides of variable stars which the above observatory undertook to compute, with the aid of grants from the I. A. U. and the Polish Minister of Education.

It includes 44 eclipsing variables with period less than  $18^d$ , 219 with period between  $18^d$  and  $10^d$ , and 26 with periods exceeding  $10^d$ . Elements, but not ephemerides, are given for 32 other stars. The ephemerides are heliocentric. For reasons of economy, stars south of Decl  $-23^\circ$  are omitted this year, also the index of ephemeris-stars.

The volume also contains certain coefficients for calculating precessions and the times of occultations of stars by the moon for five observatories in Poland. The explanations, and the headings of tables, are in flexible Latin, which is easy to read.

## Research on Springs \*

THERE are few people at the present time who are not interested in springs of some kind. That large section of the general public which uses the automobile, either for business or pleasure, generally finds at some time or other that the breakage of a circular spring round a valve stem or of a flat spring on the suspension system may be responsible for an amount of inconvenience out of all proportion to the seriousness of the accident.

Even government departments are liable to such troubles, and both during the War and for some years after, the Chief Inspector of Mechanical Transport of the War Office directed attention to the unsatisfactory position in relation to the design and performance of laminated springs for mechanically propelled vehicles. Failures of valve springs in aircraft engines were reported by the Air Ministry, and both the Admiralty and the War Office were experiencing difficulties with spiral springs. In the motor-car trade there was much trouble associated with the use of valve springs on high-speed car engines and generally where the working conditions were severe.

Due to the representations made to the Department of Scientific and Industrial Research, a Springs Research Committee was appointed in 1922, with the main object of carrying out such inquiries and researches as would result in the improvement of the materials and design of laminated and spiral springs. Since that time much work has been done by the different sections of the Committee, and the results of their investigations have been published from time to time. In the Report just issued, a general survey is made of the whole of the Committee's work and the definite conclusions to be drawn from it are summarised.

It will be found that the field covered by the Com-

mittee is a very wide one. Naturally the researches into the properties of spring material bulk largely in the Report, but much work has also been done in perfecting methods of testing complete springs and of finding the oscillating and loading conditions to which springs are subject under road service.

The most striking conclusion reached is that, with springs as ordinarily manufactured and used, the high stress-resisting properties of which the spring material is capable are not realised. Spring material of many types has been tested under a wide variety of conditions, and has shown itself to be capable of resisting wide ranges of repeated stress for long periods. When, however, this material is converted into springs, breakage occurs at stress ranges of from about one-quarter to one-half of what should have been resisted.

The explanation given for this surprising discrepancy is that a surface weakness is developed during the heat treatment and other manufacturing processes. Experiment has shown that this deleterious surface layer is very thin, and that the full resistance value of the material can be regained by machining about one-sixteenth of an inch from the surface of the spring. With spring steel wire the same conclusions hold, in all grades of wire tested the 'surface effect' was evident even when the wire had been manufactured under special conditions. It is, therefore, not surprising that the Committee recommends that manufacturing methods should be developed for the production of spring steel in plates or wire which shall utilise the full intrinsic fatigue strength of the material.

The Report should be of value both to the user and manufacturer of springs. It is an excellent illustration of the value of co-operation between science and industry, since, largely as a result of a systematic and detailed programme of research, both an explanation and a remedy have been found for a trouble responsible in the past for many serious consequences.

## The Dating of Pueblo Ruins in Arizona

EXCAVATIONS undertaken on four sites in Arizona, Kin Tiel and Kokopnyama, north of the Little Colorado River, and Pinedale and Showlow in the forested area to the south, have furnished evidence which will now make it possible to date the phases of Pueblo culture with accuracy over a period of 1200 years.

The researches in dendro-chronology, as applied to Pueblo archaeology, which were undertaken by Dr. A. E. Douglass at the invitation of the National Geographic Society while the famous ruins of Pueblo Bonito were under excavation by one of its expeditions, have established two sequences of ring records in the course of three 'Beam Expeditions' to the Pueblo area.

For one of these the coincidence and overlap of the annual rings in pine log beams from the still inhabited Hopi village of Oraibi were worked out, in accordance with the system elaborated by Dr. Douglass, from the normal and subnormal growth of rings according to rainfall, to show a complete historical sequence back to about A.D. 1260. By the same method a prehistoric sequence was established, extending back over 580 years on the evidence of beams from the Citadel ruins at Mesa Grande and Pueblo Bonito, thus going back into the third of the five periods of Pueblo culture, of which the fifth and last extends from the Spanish conquest in the sixteenth century to the present day.

The excavations at the four sites mentioned were undertaken in the hope of finding a link which would connect the prehistoric and historic sequences and substitute an absolute dating for the relative dating of the earlier period. It was thought that such a link would be provided by the study of a certain transient type of Pueblo pottery, for which no date was available, but which, it was thought, would furnish a clue to ruins immediately antedating the still inhabited Oraibi village. A reconnaissance of twenty prehistoric villages was made before the four sites in question were selected.

The accounts of the chronological and archaeological results obtained by Dr. Emil W. Haury and Mr. Lyndon Hargrave at Showlow and Pinedale, and by the latter at Kin Tiel and Kokopnyama (*Smithsonian Miscellaneous Collections*, vol. 82, No. 11), provide some indication of the far-reaching effect of the application of an absolute and accurate chronology to the investigation of Pueblo antiquities. So far as the main objective of the expedition is concerned, timbers were recovered which linked together the two date sequences and carried back the tree ring calendar to A.D. 700. A beam, to which the field notation H.H. 39 has been given, was found at Showlow which proved the key beam converting the relative dating into an absolute chronology. The outer rings could be read at about A.D. 1380, while its central ring dated at A.D. 1237. The innermost rings coincided with the

last rings of the prehistoric chronology and the outer rings were readily identifiable with the thirteenth and fourteenth century records of the historic sequence. Further excavations yielded more logs which confirmed the record of the key beam.

As the last rings of any given beam give the cutting date, when it shows the true outside, it is obvious that it also gives an approximate date for the erection of the building in which it was used, provided there is no evidence of re-use. Thus at Showlow it was possible to reconstruct the history of the building. The beams showed a period of reconstruction at about A.D. 1380, with periods of activity at 1204 and 1272, while re-used beams gave dates ranging from 1175 to 1356.

The manner in which the archaeological and chronological conclusions confirm and supplement one another is well illustrated in the reports of the investiga-

tions. There are, for example, three horizons which are dated respectively at A.D. 1204 (Showlow), 1290 (Pinedale), and 1375 (Showlow), and the sequence of the styles of pottery associated with each is confirmed. The chronological evidence indicates the length of time by which culture features survive in a marginal area while dying out in the centre of origin. Thus Chaco traits are shown to exist in the pottery a hundred years after the Chaco Canyon culture ceased to exist. Further, it confirms the views of those who argued on the basis of stratigraphy that lead glaze existed in the Pueblo culture before the advent of the Spaniards, as against those who maintained that it was improbable that it could have been used by the Pueblo potters in the prehistoric period. Dendrochronology shows that it was employed fully two hundred years before the arrival of the Conquistadores.

### The Climate of Japan

IN the *Bulletin of the Central Meteorological Observatory of Japan*, vol. 4, No. 2, Prof. T. Okada gives a very thorough discussion of the climate of Japan. It is divided into three sections, entitled, "Climatography", "Climatology", and "Climatic Tables".

The first section opens with an interesting discussion on general lines of the main features of the climates of the different climatic zones into which the country can conveniently be divided, and outlines the main factors that are responsible for the primary characteristics of these. Each region is then discussed in greater detail. In the second section the method of arrangement is not geographical, but according to each climatic element—for example, air temperature, wind direction and speed, rainfall, and so on. The last section is entirely occupied with tables showing the seasonal variation of different elements, it is followed by a general index, and then by thirty-five plates setting out graphically the seasonal or geographical variations of the elements discussed earlier in the work. The magnitude of the work and the wealth of detail that it gives about a region where the organisation of climatological work on modern lines has naturally been undertaken at a later date than in Europe make it indispensable as a work of reference for professional meteorologists.

The climate of Japan, owing to the peculiar situation of that country, at no great distance from those parts of Asia which present the greatest contrasts between summer and winter to be found anywhere in the world, is a particularly interesting one; it provides an example of what Okada describes as "an extreme climate characteristic of a continent" in spite of its insular position. The winter is dominated by the prevalence of cold air flow from China. This flow does not take place across a sufficient width of sea for the latter to have very much tempering effect, but although the wind is often very strong, there is time

enough for the air to acquire a considerable amount of water vapour, and this tends to condense when the air ascends to pass across the land. The result is that "gloomy weather with snowfall prevails on the side facing the Japan Sea, and rain showers occur almost every day in the Ryūkyū or Loochoo Islands and northern Formosa. Therefore, on this side of Japan proper, snow lies deep on the ground and a thick veil of clouds overcasts the sky. Fine days are phenomenal." On the Pacific side, however, fine weather generally prevails at this season. In the islands to the south of Japan proper the influence of the Asiatic winter monsoon is overshadowed by that of the warm ocean, and luxuriant tropical vegetation can flourish.

During the summer, when the Asiatic area of high pressure disappears, to be replaced by relatively low pressure and a complete change of wind circulation, an inflow of air takes place, which crosses Japan mainly from between south and east; it is feeble and less constant than the winter monsoon, especially during the principal rainy season called the Bai-u, which comes in late June and early July. These winds do not give rise to the contrasts of climate on the windward and leeward sides of the islands found in winter, nor is there so much variation of temperature with latitude; the result is a generally hot and humid climate, appropriate to maritime conditions in those latitudes.

In conclusion, some reference must be made to a very noticeable feature of all except the southern sea-dominated parts, and that is the shortness of the spring and autumn seasons. In the north, snow may still be lying early in May, although June generally brings the heats of summer; autumn does not extend much beyond the month of October, for the cold winter winds are usually well developed by November.

E. V. N.

### Weather Forecasting

IN his Friday evening discourse at the Royal Institution on Feb. 5, Dr. G. C. Simpson discussed weather forecasting. In 1859, Admiral FitzRoy, who was then the head of the department of the Board of Trade which had recently been established to study marine meteorology, commenced to collect weather reports by telegraph from a number of ports in the British Isles, and so a new science was created and a new term added to the English language. FitzRoy's innovation was not approved by scientific men, and on his death in 1865 forecasting ceased.

The public had, however, found the forecasts useful, and considerable pressure was brought to bear on the Meteorological Office to recommence the forecast service. A new attitude was possible owing to the introduction of the synoptic chart showing the distribution of pressure by isobars, the lines with which we are now so familiar on the published weather maps. It had been found that isobars could be classified in a number of types of which the most familiar are the cyclone and the anticyclone. This remained the basis of forecasting until the War, and it is still largely

employed. The method is entirely empirical and needs no knowledge of the physics of the atmosphere.

We now recognise that weather is produced by the bringing together of great masses of air from polar and tropical regions by the general circulation of the atmosphere. Such masses of cold and warm air do not readily mix, but overrun or undercut one another along 'fronts' which can be traced for hundreds of miles on the synoptic charts. The recognition of fronts has given the forecaster a powerful new tool for the study of what is actually taking place in the atmosphere, and has greatly improved the short period forecasts, especially those for aviation.

A synoptic chart which extends only over a single country is not of much value for forecasting, it is necessary to know the weather conditions over a much larger area. To meet this need there is very close international co-operation between the official weather services of the different countries. At certain specified times each day observations are taken at forty-five stations in the British Isles and on a number of ships on the Atlantic and telegraphed to London.

The same procedure is taking place in every other country. The meteorological office in Paris takes in these national messages from countries in western Europe, and the German meteorological service does the same for central and northern Europe, while Moscow deals with the whole of the great area of the U.S.S.R. Paris, Hamburg, and Moscow then reissue the messages they have collected from wireless stations sufficiently powerful to be heard all over Europe, according to a programme carefully drawn up by an International Committee. In this way information from more than five hundred stations in an area extending from Spitsbergen and Greenland in the north to Morocco, Algeria, and Egypt in the south, and from the middle of the Atlantic in the west to Russia and Palestine in the east is available in every meteorological office in Europe within two hours of the time at which the observations were taken. The whole programme of collecting and disseminating the observations is repeated three times a day by most countries, at 7 A.M., 1 P.M., and 6 P.M. G.M.T., and a certain number of countries add another set of observations at 1 A.M.

Unfortunately, no method has been found for expressing the success of weather forecasts by giving the percentages of failures and successes, but those who have to examine every day's weather in the light of yesterday's forecast know that there has been an appreciable increase in the accuracy of the forecasts and also in the amount of detailed information it is possible to include in them.

### University and Educational Intelligence

CAMBRIDGE—Prof P. Debye, of the Physical Institute at Leipzig, has been appointed Scott lecturer for the year 1932.

Dr E. B. Worthington (Balfour student) will lecture on Feb. 17, at 5 P.M., in the zoological lecture room, on the "Great Lakes of Africa".

A COURSE of eight bi-weekly lectures on the "Optical Principles of Television" will be given by Dr W. D. Wright at the Imperial College of Science and Technology, South Kensington, London, S.W.7, on Tuesdays and Thursdays at 4 P.M., commencing on Feb. 23. Further information can be obtained from the Registrar of the College.

THE Council of the University of Melbourne has passed a resolution expressing to Mr F. Chapman,

Commonwealth palaeontologist, on his retirement from the position of part-time lecturer in palaeontology after twelve years' service, its thanks for the help which by his wide knowledge and great experience of palaeontology he has rendered to the Geological Department of the University.

EDUCATION during the past ten years in Porto Rico is reviewed in a leaflet recently issued by the U.S. Office of Education, Washington. The review is of more than local interest by reason of the description it contains of a seemingly successful experiment in rural education of a vocational type. Thirteen consolidated rural schools have been established for pupils aged eleven years and upwards, for whom the education hitherto provided in the fourth and higher grades in Porto Rican schools offers but little hope of increasing their earning capacity. In these new 'second-unit' schools only half of the day is devoted to academic subjects, the other half being given up to vocational work, namely for the boys, agriculture, animal husbandry, woodwork, house-wiring, tin-smithing, auto-mechanics, shoe-repairing, hair-cutting, clay work, and toy-making, for the girls, cooking, sewing, and hand and machine embroidery and lace-making, and for both, hand-weaving. Agriculture is a required subject for all boys and home economics for all girls. The boys raise a large variety of vegetables, which are sold or consumed in the school lunch-room, one-third of the cash value of produce sold being given to the boys who raised it. The children are encouraged to cultivate home gardens, of which there are more than 15,000. As a result of this system the quantity and quality of fresh vegetables available to the rural communities have improved and family incomes increased. The boys are taught also to plant the principal crops and to raise pigs, chickens, rabbits, pigeons, and goats. The breeds are being rapidly improved. The lessons in cooking aim at a diet based largely on Porto Rican produce, and the results are tested in the school lunch-room. It is noteworthy that this experiment, which is one of the fruits of an educational revival brought about by a survey conducted in 1925 under the direction of Dr Paul Monroe of Teachers' College, Columbia University, was undertaken during a period of severe retrenchment in educational expenditure.

### Calendar of Geographical Exploration

Feb. 16, 1623—Arnhem Land

Jan Carstensen on an expedition in which two ships, the *Arnhem* and the *Pera*, took part, sighted the snowy mountain chain of central New Guinea. Mt Carstensen, more than 15,000 feet in height, takes its name from him. The two ships became separated. Carstensen in the *Pera* discovered and named several rivers in the York peninsula. Although the lands discovered by the *Arnhem* are not exactly known, the vessel explored the region between 9° and 13° S in that part of the Northern Territory, Australia, now known as Arnhem Land.

Feb. 16, 1816—The Congo Cataracts

Capt Tuckey, with a party which included a botanist, a geologist, a naturalist, and a comparative anatomist, left England commissioned by the Government to ascend the Congo. Another party was sent to the Niger, and it was hoped that the two might eventually meet, Mungo Park's explorations having failed to clear up the question of the separate identity of the Niger and the Congo. Tuckey's party reached the first cataract of the Congo and thence attempted

exploration by land. Disease, however, overtook the party and they returned to the ship, where Tuckey and others died. The companion expedition, which had landed on Dec 14 at the mouth of the Rio Nunez, midway between the Gambia and Sierra Leone, met with equal disaster, disease and discord with the natives resulting in the death of most of the party.

#### Feb 18, 1865 —Colonel Pelly in the Nejd

Colonel Lewis Pelly, British resident at Bushire, set out from Koweit with a small caravan, and after five waterless days in the desert reached the wells of Orma at the foot of Jabal Tueik. On March 5 he reached Riyadh. On the return journey the guide led Pelly's party by a route considerably to the north of Hofuf, all the main lines of relief were found to run north and south, and seven distinct ridges had to be crossed in the descent from the Tueik plateau to the coast. He covered some previously unexplored regions, but was unable to take as many measurements and observations as he had hoped owing to the need for haste in view of political difficulties. Pelly was the first representative of a European government to venture into the centre of the Arabian peninsula openly avowing the nature of his mission.

#### Feb 20, 1844 —Between the Mississippi and the Pacific

J C Frémont, one of the greatest of American explorers, reached the summit of the snow-covered Sierra Nevada mountains. He had started out in 1842 to explore the route beyond the Mississippi as far as South Pass in Wyoming. He ascended the second highest peak of the Wind River mountains which now bears his name and in the following year reached the Oregon settlements. Thence he turned south and east via the Klamath lakes to north-western Nevada and the Truckee and Carson rivers, covering much previously unexplored country. After crossing the Sierra Nevada he spent the rest of the winter on the Sacramento River, and returned round the southern end of the range to the Great Salt Lake, following the old Spanish trail from Santa Fé to California. Frémont had accompanied J N Nicollet, the French explorer, in his survey (1835-40) of the country between the upper waters of the Missouri and Mississippi rivers. In 1841, Frémont headed an expedition to the Des Moines River and thus completed Nicollet's map. His explorations opened up a great part of the country between the Mississippi valley and the Pacific Ocean. Frémont had a varied career, afterwards becoming soldier, politician, and multi-millionaire.

#### Feb. 20, 1848 —Northern Arabia

G. A Wallin, a distinguished Arabic scholar, who afterwards became a professor in the University of Helsingfors, left Muweila on the second of his famous journeys in northern Arabia, travelling disguised as a learned Arab sheik. Striking inland across the unexplored granite mountains, he reached Tebuk, an ancient village on the Syrian pilgrim route. Thence he proceeded to Tema, crossed a tongue of the Nafud, and after a month's stay at Hail accompanied a party of tribesmen to Meshed Ali and returned via Bagdad. On a previous journey Wallin had started from Cairo and travelled via Maan over the Hamad to Jauif. Thence he had crossed the Nafud, seen the isolated grey granite chains of Jabal Aja and Jabal Selma, and penetrated to Hail. Of Medina and Mecca which he also visited he left no detailed account. Although he took no instruments, his full and minutely accurate reports gave a clear picture of the regions through which he passed, many of them never before visited by a European.

## Societies and Academies

### LONDON

Royal Society, Feb 4 —J R Baker and R. M Ranson. Factors affecting the breeding of the field mouse (*Microtus hirtus*)—(1) Light. The shortening the daily period of exposure to light from fifteen hours to nine hours almost stops reproduction in the field mouse, *Microtus hirtus*. The female is chiefly affected—T. H Bissonnette. Modification of mammalian sexual cycles, reactions of ferrets of both sexes to electric light added after dark in November and December. Male and female ferrets were subjected to doses of electric light during the night between October and January. Full œstrus was induced in the females in 38-64 days and successful coitus in 59-70 days. In the males interstitial cells were stimulated and copulation took place in 59 days, but no mature sperms were found even after 71 days. Birds differ from mammals in that the males are more responsive to doses of light than females. It is suspected that, with both birds and mammals, light may act through modifying anterior lobe activity, or susceptibility to it—R N Salaman. The analysis and synthesis of some diseases of the mosaic type. The problem of carriers and auto-infection in the potato. As a result of both analytical and synthetic methods it has been possible to ascribe compositions in terms of X, Y, and Z to certain definite clinical virus diseases. The reaction of a virus complex is not the mere summation of that of its two constituents, but rather a linked group the strength of which varies according to the complex and the internal environment of the plant. At times a complex may break up either in an infected or a carrier plant, and one or other element becomes recognised as such. If this takes place in a carrier plant it is known as auto-infection—C. C John. The origin of erythrocytes in herring (*Clupea harengus*). During the first five months of development, the herring is devoid of red blood. The demersal egg hatches into a tiny larva in which the heart is at first a simple two-walled tube divided into two parts by a narrow constriction in the middle. The vascular fluid is colourless and does not contain any corpuscles. From deep water the larva migrates into mid water, and later to the coast. During this period the endocardium develops into a syncytial sponge-work in which numerous large nuclei develop, these ultimately migrate to the surface of the sponge-work and bud off into the vascular fluid as mother-cells of the red-blood corpuscles. At the 35 mm. stage the larva is at first rather opaque and the blood is colourless. When metamorphosis starts, a silvery sheen appears on the dorsal surface, and the body becomes opaque and the blood commences to turn red. A similar condition occurs during the development of the eel, in teleosts in general the blood originates from the intermediate cell mass during the early embryonic stage, but in herring the hæmocytopoietic function is confined to the endocardium until the spleen develops.

Physical Society, Dec 4 —C F B Kemp. Some properties of the sound emitted by airscrews. A condenser-microphone amplifier system has been employed to determine the intensities and directional properties of the first six harmonics in the sound of rotation of an airscrew operating at zero rate of advance and actuated by a silenced engine. The sound-energy associated with the frequencies considered is 18 watts, the fundamental (first harmonic) being responsible for 50 per cent of this, while the first three harmonics together contribute 90 per cent.

Maximum intensity occurs at  $15^{\circ}$ - $30^{\circ}$  behind the plane of rotation, and in this region the sound-output is particularly steady. Large intensity-fluctuations occur along the axis of the slip-stream. The intensity follows the inverse square law of distance at points farther than 200 ft from the airscrew centre, a 2.4-power law holding approximately for nearer points.—J H Awbery and Ezer Griffiths. The basic law of the wet-and-dry-bulb hygrometer at temperatures from  $40^{\circ}$  to  $100^{\circ}$  C. The relative humidity was measured both by absorbing and weighing the moisture in a known volume of air and by the dew-point method. The results are finally expressed by means of a skeleton table for the wet-and-dry-bulb hygrometer in the temperature range referred to.—J H Awbery. The water-content of saturated air at temperatures up to  $100^{\circ}$  C. The water-content of air which is just saturated has been measured at temperatures from  $29^{\circ}$  to  $94^{\circ}$  C by absorbing the moisture and weighing it. To obtain saturation, air was bubbled through water in a thermostatically controlled bath. In some experiments the air was initially below saturation, whilst in others it was not and contained more moisture than would be necessary for saturation at the bath temperature.—Ezer Griffiths and J H Awbery. (1) The specific volumes of some gaseous refrigerants, (2) the latent heat of some refrigerants. The method used consists in permitting the liquid to evaporate repeatedly into an exhausted vessel so that automatically the vapour is under saturation pressure. The volume of the vessel is known, and the weight necessary to fill it is found from the decrease in weight of the liquid. The substances studied were sulphur dioxide, dichloroethylene, ether, pentane, and trichloroethylene. The latent heats of evaporation of ethyl chloride, methyl chloride, sulphur dioxide, pentane, and dichloroethylene have been measured over the temperature ranges lying between  $-18^{\circ}$  C and  $+25^{\circ}$  C. The method used is an electrical one, in which a known amount of energy is supplied at constant temperature and the mass evaporated is obtained by weighing.

## EDINBURGH

Royal Society, Jan 11.—Sir E. A. Sharpey-Schafer and W A Bain. The employment of intra-cardiac injections of adrenaline in asphyxia. In asphyxia caused by occlusion of the trachea, intra-cardiac injection of adrenaline has a marked effect in promoting recovery of the circulation. Even if the heart has ceased to beat for a short time, it will contract strongly and rapidly as the result of such injection, which should be made through the chest-wall, directly into the heart muscle. The adrenaline not only affects the heart but also the arteries, causing them to contract and thus keeping the blood pressure raised. Breathing recommences as soon as the circulation is restored, and although at first slow and deep, the respiratory movements gradually resume their normal character. The effects of the adrenaline injection are assisted by artificial respiration produced by intermittent pressure on the abdomen and lower part of the thorax.—B P Wiesner and Miss N M Sheard. Studies on maternal behaviour and its endocrine basis. Maternal behaviour in the albino rat can be prolonged by regularly replacing grown-up litters by small ones. The stimulus value of young with respect to maternal responses is inversely proportional to the age of the young. Determination of the age of the oldest young which is still retrieved by a female represents a method for evaluating the intensity of the retrieving drive. Oophorectomy before or after parturition does not interfere with the development or persistence of maternal behaviour. Injection of ovarian hormones in nulliparous females so far has

not produced maternal behaviour. Injection of ammonia extracts from the anterior lobe of the pituitary produces maternal behaviour of varying intensity in both oophorectomised and intact nulliparous females in a high percentage of cases.—H Briggs. Graphical classification of carbonaceous minerals: the place of the constituents of common coal. Reference was made to the method of classification of carbonaceous minerals developed in a previous paper read in March 1931. Making use of a considerable number of published analyses, the method is applied to each of the constituents of coal (vitram, duram, and fusam) in turn. The resulting charts show the relative state of evolution of these components in any seam. Generally speaking, the fusam of any given bituminous coal is more advanced in rank than the other components. With an anthracite, however, the disparity in rank is less, the vitram having caught up with the fusam, and having sometimes, indeed, become the more anthracitic of the two.—A C Aitken. On the orthogonal polynomials in frequencies of type B. Neither of the two types of series which are commonly used to represent probability or statistical frequency, the so-called series of type A and type B, is free from irregularity in the order of magnitude of its terms. In 1928, C V L Charlier conjectured that in the case of type A this defect might be removed by expressing the logarithm of frequency as a series of Hermite polynomials. The correctness of this was confirmed by Dr A Oppenheim and the present author in 1931. An analogous procedure is now shown to be valid for the case of type B.—D M Y Sommerville. Isohedral and isogonal generalisations of the regular polyhedra. An isohedral polyhedron means one whose faces are all congruent or mirror images, and an isogonal polyhedron one whose vertices have equal corresponding plane angles and dihedral angles. A detailed examination is made of all isohedral or isogonal polyhedra, in Euclidean and non-Euclidean geometry, which are isomorphic with the five regular polyhedra. Of special interest are the isohedral icosahedron and the isogonal dodecahedron, neither of which, unless it is regular, has either a circumscribed or an inscribed sphere. It is of interest also to note that, while in Euclidean geometry two rhombic hexahedra exist with the same faces, differently arranged, in non-Euclidean geometry the only hexahedron whose faces are symmetrical quadrilaterals is the regular hexahedron. Further, four different isohedral octahedra can be constructed with the same triangular faces, differently arranged.

## PARIS \*

Academy of Sciences, Dec 28.—Mlle Lucienne George. The relations of the Gnetales with the Dicotyledons and the Gymnosperms.—E. Mège. The taxonomic values of the leaf characters of cereals.—H Colin and M Quillet. The composition of the jelly of *Auricularia mesenterica*. Hydrolysis gave mannose and arabinose. No ketonic sugar was found.—Marcel Chopin. Study of commercial colloidal complexes: application to indiarubber. A detailed account of a method of preparing rubber films for mechanical testing: concordant and repeatable measurements can be obtained with films prepared by the method indicated.—A Damiens and Mlle S Baignan. The normal bromine in plants: food grains, wheat, bread. The seeds of about twenty plants were examined, and bromine was present in all, with the exception of rice and beans, in which the halogens are present in traces only. The ratio of bromine to chlorine was not found to be constant, but varied from  $85 \times 10^{-3}$  (lentils) to  $2.8 \times 10^{-3}$  in wheat.—J André Thomas. Researches on the obscure vesicles of *Sipunculus*. The reproduction by budding. The observations described lead to the

\* Continued from p. 215

conclusion that the vesicles of *Sipunculus* are special stages in the evolution of a new parasite, which give rise by budding to young vesicles—Alphonse Labbé The food factor in the specific coloration of eolidians—Raymond Hovasse Radiolaria and Silicoflagellæ—Mézincesco The rôle of the non-essential amino-acids in the partial supply of the specific endogenous nitrogen consumption—F Marceau and L Acolat General considerations on the circulation of the venous and arterial blood in the three-cavity hearts of vertebrates and the measurement of the degree of their admixture—F Maignon and M A Chahine The nitrogen balances in white rats submitted to egg albumin fat and to egg albumin glucide regimes. Fats exert a favourable effect on nitrogen metabolism and result in a better nutritive yield of the proteins from the point of view of proteosynthesis—A Leulier and F Postic The influence of nitration and of amination on the physical and physiological properties of methylphenylmalonyl urea (rutonal) and of ethylphenylmalonyl urea (gardenal or luminal) The introduction of the nitro or amino group into the benzene nucleus of hypnotics of the phenylmalonyl urea group lowers the partition coefficient between water and olive oil The hypnotic effect is also lowered—Georges Bohn and Mme. A. Drzewina The morphogenic action of betaine on the eggs and larvae of the sea-urchin—Ch Hervieux The search for indoxyl (indican) in the milk of cows and goats Some authors do not admit that indoxyl colouring matters can, in the normal state, pass into the milk The experiments described, carried out on twenty-five specimens of normal milk, gave positive reactions for indican with thymol in every case—Edouard Chatton and Andre Lwoff The conception of an apostome ciliate (Fectinigeridae and Opalinopsidae) Proofs of its validity—E Fernbach The period of preservation of solutions of tuberculin A solution of tuberculin (dilution  $\frac{1}{4}$ ) made up in 1907 was proved to be active in 1913, nearly six years later A further test of the same solution made twenty-five years after dilution showed that it had not lost its activity The solution was kept in sealed sterilised tubes, at 20° C, and in the dark—Jean Régner and Robert David Contribution to the study of microbial multiplication The modifications in the composition of different liquid culture media brought about by the microbial increase (pyocyanic bacillus) It does not appear that the arrest of growth is due to exhaustion of the food supply The chemical changes produced in the media are not proportional to the bacterial growth.

## SYDNEY

Linnean Society of New South Wales, Oct 28—Lilian Fraser The reaction of *Viminaria denudata* to increased water content of the soil The shrub can survive a condition of soil saturation for extended periods and reacts to this condition by the production of both upright and 'knee-bend' pneumatophores, and by the production of a secondary aerenchyma in submerged roots, which is cut off from a phellogen arising in the pericycle, replacing the cork layers of the normal root—F A Craft The physiography of the Shoalhaven River valley (6) Nerriga Consideration is given to the origin and significance of the drift, and a special study of land forms in various strata is made The valley types are dated with reference to late Tertiary basalt, and it is hoped that this will permit the identification of similar forms in places from which basalt is absent—A H S Lucas Notes on Australian marine algae (6) Description of six species of marine algae as new; they belong to the genera *Gelidium*, *Pterocladia*, *Nitophyllum*, *Champia*, *Lessonia*, and *Caulerpa*

## Forthcoming Events

## Societies

## FRIDAY, FEBRUARY 12

- ROYAL ANTHROPOLOGICAL INSTITUTE (Sociological Research Committee) (at 52 Upper Bedford Place), at 4—Mrs Seligman The Method of Exhibiting Genealogical Data—C W M Hart Is it correct to regard all Australian Tribes as on the same Economic Level?  
ROYAL ASTRONOMICAL SOCIETY, at 5—Anniversary Meeting  
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—Prof H A Harris The Comparative Anatomical Aspect of Pre-Natal, Infantile, and Adult Disease in Man and Animals, with special reference to Bone Growth (2) (Hunterian Lecture)  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Sir John Cadman Petroleum A Record of Achievement in Applied Science

## MONDAY, FEBRUARY 15

- ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 4—Wilfred Trotter Hunterian Oration  
INSTITUTION OF ELECTRICAL ENGINEERS (Mersey and North Wales (Liverpool) Centre) (in Arts Theatre, Liverpool University), at 7 30—Prof J K Catterson-Smith Everyday Uses of Electricity (Faraday Lecture)

## TUESDAY, FEBRUARY 16

- ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15—Sir William Bragg Recent Work on Crystal Analysis (2)  
ROYAL SOCIETY OF MEDICINE, at 5 30—General Meeting of Fellows

## WEDNESDAY, FEBRUARY 17

- BRITISH ACADEMY, at 5—Prof H. J. Fleure Archaeology and Folk-Tradition (Sir John Rhys Memorial Lecture)  
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—Prof W E Le Gros Clark The Structure and Connexions of the Optic Thalamus (1)  
INSTITUTION OF ELECTRICAL ENGINEERS (Sheffield Sub-Centre) (at Royal Victoria Hotel, Sheffield), at 7 30—J M Donaldson Presidential Address  
FOLK-LORE SOCIETY (Annual General Meeting) (at University College), at 8—Presidential Address

## THURSDAY, FEBRUARY 18

- ROYAL INSTITUTION OF GREAT BRITAIN, at 5 15—Prof. J. B S Haldane Heredity in Man (1)

## FRIDAY, FEBRUARY 19

- INSTITUTION OF CHEMICAL ENGINEERS (Annual Corporate Meeting) (at Hotel Victoria, Northumberland Avenue), at 12 noon—W A S Calder Control of Industry (Presidential Address)—At 2 15—Dr Ezer Griffiths Thermal Insulation  
ROYAL COLLEGE OF SURGEONS OF ENGLAND, at 5—Prof W E Le Gros Clark The Structure and Connexions of the Optic Thalamus (2)  
ROYAL INSTITUTION OF GREAT BRITAIN, at 9—Prof C F Jenkin The Mechanics of Shifting Sands

## Public Lectures

## FRIDAY, FEBRUARY 12

- ST BARTHOLOMEW'S HOSPITAL MEDICAL COLLEGE, at 5 30—Dr L Findlay The Feeding and Nutritional Disease of the Infant (3)  
UNIVERSITY COLLEGE, at 5 30—Prof Sir Reginald Fleming Johnston China in the Ancient World

## SATURDAY, FEBRUARY 13

- HORNIMAN MUSEUM (Forest Hill), at 3 30—Mrs Olwen Brogan Town-Life in the Roman Empire.

## MONDAY, FEBRUARY 15

- GUY'S HOSPITAL (in Physiological Theatre), at 5—Dr. A E Barclay The Use of X-Rays in Physiological Investigations The Mechanism of Swallowing

UNIVERSITY OF LEEDS (in Chemistry Lecture Theatre), at 5 15—Prof P. Kapitza Phenomena in Strong Magnetic Fields

KING'S COLLEGE, LONDON, at 5 30—Prof S H Hooke The Myth and Ritual of the Old Testament and the Culture Patterns of the Ancient East Traces of Early Myth and Ritual in Canaan.

#### TUESDAY, FEBRUARY 16

UNIVERSITY COLLEGE HOSPITAL MEDICAL SCHOOL, at 5 15—Prof A E Boycott. Hypertrophy and Atrophy (2)

INSTITUTE OF INDUSTRIAL ADMINISTRATION (at Institute of Hygiene), at 6 30—E S Byng. Elimination of Waste in Industry

#### WEDNESDAY, FEBRUARY 17

ROYAL INSTITUTE OF PUBLIC HEALTH, at 4—Dr A R Neligan The Organisation of Treatment for Industrial Rheumatism

KING'S COLLEGE, LONDON, at 5 15—Prof J Holland Rose The Mediterranean in Ancient History (5) The Mediterranean Empire and its Influence on Civilisation  
BELFAST MUSEUM AND ART GALLERY, at 8—Dr. R H Hunter. The Wonders of the Human Body.

#### THURSDAY, FEBRUARY 18

UNIVERSITY OF LEEDS (in Physics Lecture Theatre), at 2 30—Sir William Bragg The Laboratory and the Citizen

UNIVERSITY COLLEGE, at 5 30—Prof E G Gardner Campanella and the City of the Sun—Sir J J Thomson. Physical Lines of Electrical Forces and their Application to the Interpretation of the Electromagnetic Field (1).  
MEDICAL SOCIETY OF LONDON—Dr J. D Rolleston Benjamin Ward Richardson, his Life and Work (Chadwick Lecture)

#### FRIDAY, FEBRUARY 19

UNIVERSITY COLLEGE, at 5 30—Sir E Denison Ross The Unification of Asia under the Mongols

ROYAL VETERINARY COLLEGE, at 5 30—T. M. Doyle: Diseases of Birds due to Filterable Viruses (1).

#### SATURDAY, FEBRUARY 20

MATHEMATICAL ASSOCIATION (London Branch) (at Bedford College for Women), at 3—Discussion of Members' Topics

HORNIMAN MUSEUM (Forest Hill), at 3 30—H N Milligan. Nature Studies on the Sussex Coast.

## The Supply of Biologists\*

THE Committee of the Economic Advisory Council appointed in 1930 to "consider the obstacles which stand in the way of the education and supply of biologists for work in this country and overseas, and to submit recommendations for the removal of such obstacles", has recently issued its Report. This is based on evidence obtained from an exhaustively diverse body of witnesses, and deals with every aspect of the problem, including even a brief appreciation of the value of natural history.

The general public undoubtedly as yet fails to realise that, other than in the medical profession, there exist in Government services, in industry, and in teaching a number of posts which are open only to biological workers. This failure is due to lack of information. There is no machinery for placing before potential candidates, their parents, and schoolmasters any comprehensive statement of the various classes of biological Government posts that are likely to be vacant at any given date, together with information as to salaries and prospects of promotion, nor is there co-ordination among the departments employing biologists in Great Britain.

A similar uncertainty with regard to biological posts in the Colonial Empire—the largest employer of biologists under the Crown—is a grave deterrent to men contemplating biological careers, there being no assurance as to the number of vacancies in any given year, nor uniformity of conditions in the terms of service offered by the several Colonial Governments. It is suggested that if there were introduced for Colonial biological appointments the same degree of certainty as already exists for candidates seeking employment in the Home and Indian Civil Services, parents, schoolmasters, and university tutors would then be in a position confidently to advise young capable biologists to compete for one of the guaranteed posts, and the supply of competent workers in biological fields would greatly increase.

Uncertainty, then, is the first obstacle. The second is the financially unattractive character of the careers offered to biologists in the Colonial Service, and the poor prospect of promotion. This deterrent would be greatly reduced if there were uniformity of conditions of service and scales of pay throughout the Colonial Dependencies, and if high administrative positions were attainable by

\* Economic Advisory Council. Committee on Education and Supply of Biologists. Report. Pp 68 (London: H.M. Stationery Office, 1932.) 1s net.

biologists possessing the necessary administrative capacity

The demolition of these two main obstacles will itself effect the reduction of the remainder "Once it becomes generally recognised that there are careers in biology, the public will turn their attention to the opportunities offered for their boys, and parents will see to it that the schools provide the instruction, once the schools give the proper position to biology in the curriculum, boys will begin to become interested, and the attractions of careers offered by biology will be weighed against those offered by classics" and other subjects. The process must, however, be gradual, over-production of suitable candidates as a consequence of excessive stimulation would result in disappointment, and would discourage further supply *Festina lente*.

Partly as a result of the foregoing obstacles, biology arrived in the curricula of schools long after chemistry and physics had become firmly established. Indeed, though its position has of late years much improved, it has not yet received universal recognition. Biology should, as an indispensable cultural element, be brought to the notice of every boy, and none should leave school without some knowledge of it. The result of this late arrival is that relatively few boys, and especially too few of the most able, have proceeded to the universities with their minds still open to biology, and at the universities they have continued on the lines of their previous studies in chemistry and physics, particularly if they held scholarships awarded for those subjects. It can scarcely be doubted that among these were some who would have found in biology their *métier*, had the subject but been included in the course of their training.

The consolidated positions occupied by chemistry and physics have enhanced the difficulty of finding a place for biology in school curricula. It has inevitably followed that the number of candidates for scholarships at the universities in these older subjects has become very great, competition has thus become severe, the standard of the examinations has risen, the schools have been driven to excessive concentration on chemistry and physics; and biology has often gone to the wall. Moreover, the biology candidate must perforce have a good elementary knowledge of both chemistry and physics, and thus, from sheer lack of time, cannot attain in his own subject to a standard commensurate with that reached in their subjects by those offering chemistry and (or) physics.

It is recommended as a remedy for this over-specialisation (1) that in the scholarship examinations at the older universities the standard in all branches of science should be definitely lower than the present in chemistry and physics, (2) that in the award, proficiency in one modern language (preferably German) should carry due weight, and (3) that the faculties of science at these universities should discourage excessive specialisation in the schools by insisting that some knowledge of biology and some proficiency in a modern language be shown by all candidates offering science for their honours degree. The adoption of these recommendations will necessitate increase in the number of teachers of biology in schools, for, unless these are forthcoming, it is impossible to create the 'pool' from which the biological services are to be maintained. At the present time, after governments, research institutions, museums, the universities, and industry have extracted their toll, there is left, as is shown by the statistical appendix to the Report, only a small remainder to teach in the schools.

The type of teacher needed in the schools is not only the specialist in biology, but also those who have taken biology as a subsidiary subject in their examination for an honours degree in science, and who are therefore competent to teach biology as a cultural subject in the ordinary curriculum. The supply of such teachers would soon be assured if the regulations governing honours science degrees were modified in the manner suggested in the Report and already quoted.

To give effect to the conclusions at which this Committee has arrived, negotiations are required between a large number of authorities, often independent of one another and regarding the problems from different points of view. The Report therefore urges that, to bring these negotiations to a successful issue, the Economic Advisory Council should recommend His Majesty's Government to invite the President of the Board of Education, in consultation with those of his ministerial colleagues who are immediately concerned, to prepare for their consideration concrete plans for the initiation and conduct of the negotiations.

The Committee has succeeded in indicating clearly where the obstacles lie, and in formulating constructive suggestions for measures by which the flow of biologists may be augmented and cleared of existing impediments. It is to be hoped that the Government will not delay to act upon its final recommendation.

## Faraday's Alloy Steels

*Faraday and his Metallurgical Researches with Special Reference to their Bearing on the Development of Alloy Steels* By Sir Robert A. Hadfield, Bt. Pp. xx+329+58 plates (London: Chapman and Hall, Ltd., 1931) 21s net

THE two papers on Faraday's metallurgical researches presented last year by Sir Robert Hadfield to the Royal Society and the British Association respectively but whetted one's appetite for more. In the volume under review the full meal is provided. In essence it is divided into two fairly distinct portions, one of which is concerned with the man himself, the conditions under which he became what he ultimately was, and the people with whom he was brought into contact. To many of the latter, through their influence upon his work and outlook, real, if indirect, credit for Faraday's own achievements is due. Great care and industry have clearly been devoted to this section of the work, with so much success that readers who neither know, nor possibly even care, about Faraday's metallurgical work will come to know a really great man.

The present study is of the greater biographical interest in that Faraday carried out his work on steel during the very early years of his research career, at the very time, in fact, when the book-binder's apprentice was being gradually transformed into one of the greatest of scientific workers. In a letter regarding his steels, written by Faraday in June 1820, he refers to "the two years that we have worked upon this subject", suggesting that this research may have been started so early as the middle of 1818. The rest of the book will be appreciated to the full only by those to whom metallurgical research, especially in the domain of special steels, is of immediate interest. To a wide circle of readers, however, some of the fascination will be felt even here.

We have already referred to the work described in Sir Robert Hadfield's papers on the samples of Faraday's steels discovered in the Royal Institution (NATURE, Jan. 9, 1932). From these, certain alloys which were known to have been made were missing, and since some, which contained large amounts of the very precious metals, were among the most interesting of all, the loss was the more deplorable. By almost incredible good fortune, the major portion of these have since been recovered and subjected to the same thorough examination as were the earlier materials. Two types alone of all the alloy steels which Faraday

made are now lacking from the samples known, namely, that containing osmium and iridium and the one containing tin.

The ten specimens forming the subject of this continuation of the research had been deposited at the Science Museum by their owner, Mr. A. Evelyn Barnard, a nephew of Jane Barnard, Faraday's adopted daughter. These consisted of a razor made from one of Faraday's own platinum steels by his collaborator Stodart, six small 'buttons' of alloys which had been melted in the famous 'blast furnace', and three samples of platinum and steel which had been welded together. In Faraday's diary for Nov. 3, 1823, is the record of the production of nine metallurgical samples, with seven of which the present materials can definitely be identified. It would have appeared out of the question two or three years ago that we should ever have known more about Faraday's steels than he himself told us in his papers, and that we should ever have been able to identify the exact melts made after the last of the metallurgical papers had appeared, and even the day and the order in which the melts were carried out, would have seemed beyond the bounds of possibility.

The total quantity of these new materials which Sir Robert Hadfield has had for investigation was less than six ounces, and the number of tests which could be made was correspondingly restricted. The amount of information which has been gathered is, however, surprising. By comparison with 'buttons' of Swedish iron fashioned into a similar size and shape—obviously a very tedious business—approximate measurements of even the magnetic characteristics have been obtained. The more interesting samples consist of platinum and rhodium alloys, each containing nearly fifty per cent of the special metal, a palladium steel with half the quantity of that metal, and three samples of steel and platinum welded together in attempts to imitate Damascus steel. The properties of the rhodium alloy are probably the most interesting. The sample, which had a mirror polish over most of the upper surface, showed, despite the century since it was made, no sign of rust. It contained only 0.12 per cent of carbon with 48.8 per cent of rhodium. One of the most outstanding physical characteristics of this 'steel' is its high magnetic permeability, which is of the same order as that of the purest commercial iron. Its Brinell hardness of 350, too, is high for an untreated material. When exposed to the Sheffield atmosphere for two days, however, slight rusting occurred at one point, so that the most resistant of Faraday's alloys, as

this was, is yet inferior to the stainless steels produced to-day

The book is unique, in no other hands could more information regarding these steels have been obtained, and it is doubtful whether in any others nearly so much would have resulted. In one direction only can anything be added to what is here contained. To the writer of this review it appears that Faraday's Bakerian Lecture on the colour of thin metallic films is worthy of credit as great as that due to his work on steel. When discussing the effects of heat upon gold leaf, Faraday showed that at a certain temperature the latter lost its metallic lustre and became transparent. In discussing the reasons for this he says ("Experimental Researches", p. 397) "As already mentioned, it might be thought that the gold leaf had run up into separate particles. If it were so, the change of colour by division is not the less remarkable, and the case would fall into those brought together under the head of gold fluids." It would not have been a long step from this observation to the conclusion, reached much later by Beilby, that polished metallic surfaces are covered with a vitreous layer of the metal and to the well-known 'amorphous hypothesis'. ### Epidemiology of Insect Pests

*Die Forstinsekten Mitteleuropas ein Lehr- und Handbuch* Von Prof. Dr. K. Escherich. Band 3, Spezieller Teil, Abteilung 2 *Lepidopteroidea*. Die "Schnabelhafte" (*Panorpatæ*), die "Kocherfliegen" (*Trichoptera*), die "Schmetterlinge" I (*Lepidoptera* I), *Allgemeines, Kleinschmetterlinge, Spinner und Eulen*. Pp. xi + 825 + 14 Tafeln. (Berlin: Paul Parey, 1931.) 57 gold marks.

IT is unfortunate that the title of this remarkable volume is misleading and may prevent the ideas put forward in it from becoming the property of general biology, to which they naturally belong.

Applied entomology is usually regarded as a purely descriptive and empirical science. Indeed, many biologists would not hesitate to consider it as not a science at all, but rather a craft. However, the last decade or two have witnessed profound changes in the methods of economic entomology, which is evolving rapidly into a real science, with its profound analysis of the causation of phenomena and the application of exact quantitative methods drawn from a wide range of other sciences. Economic entomologists of the present day study their insects against a background of the environment, and the study is not restricted to the external

phenomena of bionomics, but special stress is laid on the physiological characteristics of the insect, its limits of toleration with regard to various environmental factors, and the influence of these factors on its development and propagation. An insect is conceived as a physiological system, developing and acting in a world of physico-chemical influences, which can and must be analysed and correlated with definite phenomena of insect life. Observations in the field and subjective deductions from them are giving way to experimental studies in a laboratory and to exact investigations of the environment.

The principal aim of these studies is the discovery of the causes underlying the well-known but still largely mysterious phenomenon of the fluctuations in the numbers of an insect, which make it a pest one year, while in the next it does not attract any attention. Modern economic entomology is, therefore, assuming the character of an epidemiology of insect pests, and quantitative studies of insect population as affected by fluctuations in environmental factors from year to year attract the chief attention of entomologists. This point of view and these methods of work have proved most fruitful, and there is every promise that economic entomology will soon rise to the rank of a science the results of which will be of direct interest and of great value to very wide circles. Indeed, injurious insects, appearing as they do in enormous numbers, present an exceptionally favourable material for analytical investigations of the factors regulating the numbers of individuals of a species. Thus, insect epidemiology opens a way to a scientific analysis of one of the most central points of the evolutionary process.

The book under review hides under its unpretentious title a masterly presentation of this new aspect of economic entomology. The methods and results of epidemiological research are discussed in its general part, while the special part contains a wealth of facts, all arranged according to the epidemiological conception of entomology. The chapter on the pine moth (*Panolis flammea*, L.) can be recommended for reading to every biologist interested in general evolutionary problems, because this pest has been recently studied epidemiologically by a number of outstanding entomologists, and the results, summarised by the author in a very concise way, represent a unique picture of the life of a species as a whole and in the actual, enormously complex environment.

It is interesting to note that the results of epidemiological work on various insects tend to stress

the importance in the life of a species of the physical environment. Organic factors of control, such as predators, parasites, and diseases, in most of the cases sufficiently studied, play a definitely subordinate part, and the population of a pest is usually regulated by climatic factors, coupled with the surprisingly inadequate adaptation of insects to the vagaries of climate. It is only in some cases that the controlling influence of organic factors becomes significant, and this happens usually towards the end of an outbreak of the pest. The initial abnormal increase in numbers leading to an outbreak is always due, not to the reduced activities of natural enemies, but to the fluctuations in the course of weather, which constitutes an ever-present and continually active regulating factor. It is only fair to add, however, that the author himself is more conservative on this point than the majority of his followers in epidemiological studies.

A few minor faults may be mentioned, merely in order to stress the general excellence of the book. The problem of the selection of food plants by insects is discussed (p. 43) much too briefly for a problem of such outstanding practical and theoretical interest. The treatment of the literature has a definite bias towards German works. This is perhaps excusable so far as the special part, treating forest insects of central Europe, is concerned, but in the general chapters more attention could be directed to the valuable work of American physiologists and ecologists. For example, readers who may want to know more about the technique of physiological studies are referred to certain German books (Friedrichs, etc.), but Shelford's unique compendium is not mentioned. On p. 38, the investigations on the tarsal perception of taste by butterflies are credited to Frisch instead of Minnich, and on p. 84, an incorrect statement is made that aeroplane dusting against locusts has been developed in South Africa, while the actual paper by Mally, quoted in this connexion, refers only to experiments on dust poisons, no work with aeroplanes against locusts has ever been undertaken in South Africa, to the best knowledge of the reviewer.

A feature of the book are the numerous illustrations, including both text figures and coloured plates. Originals for most of the plates have been drawn by Herr von Kennel, a well-known authority on Microlepidoptera, and their exactitude and artistic quality of reproduction are in keeping with the generally high standard of the book.

Forest entomologists will find a mine of information on their subject in the book, workers in any

other branch of economic entomology should certainly read it, in order to obtain a definite conception of their science, the general biologist who can be persuaded to read it would have no grounds to regret the time spent on it. Economic entomologists should feel now that their science is beginning to find its place amongst other branches of biology, and this is largely due to the life-work of Prof. Escherich and his numerous pupils.

### The Geochemistry of Igneous Rocks

*The Chemical Analysis of Rocks*. By Dr. Henry S. Washington. Fourth edition, rewritten and enlarged. Pp. xvi + 296. (New York: John Wiley and Sons, Inc.; London: Chapman and Hall, Ltd., 1930.) 20s net.

DR. H. S. WASHINGTON is well known throughout the geological world as the most prolific of rock-analysts, as the author of a long series of petrographical papers, as the compiler of the records of analyses known familiarly as "Washington's Tables", and, to chemists as well as geologists, as the author of this invaluable guide to the chemical analysis of igneous rocks. The present edition has been thoroughly revised and enlarged in order to incorporate descriptions of new methods and the uses of new reagents which have, in the author's experience, proved to be simple and reliable. Details of procedure are so fully and clearly given that the book can be used with complete confidence by any capable student. Apart from the descriptions of apparatus, operations, and methods, the general discussion of the value of rock analyses and of the occurrence of the rarer elements is of great interest. It is rightly pointed out that "an analysis complete as to the subsidiary constituents may be of great value in the future or to others, even if this degree of completeness is not necessary for the end immediately in view."

A plea for completeness is worthy of particular attention at the present time, when the importance of the geochemistry of igneous rocks is just beginning to be properly appreciated. It is commonly thought, for example, that all peridotites are derivatives from basaltic magmas, notwithstanding the fact that some, like the mica-peridotites, are quite clearly independent of basaltic associations and have a very different assemblage of the rarer elements from those of basaltic origin. This is particularly noteworthy in the case of  $P_2O_5$ , F, BaO, and SrO, and consequently it may well be that detailed analysis will provide in doubtful

cases a criterion for discriminating between peridotites that come directly from the substratum and those that are merely accumulations of the early crystals of basaltic magma.

The work of Fersman shows that the nepheline-syenites and their relatives have associations of elements which differ considerably from those of both the granitic and basaltic families. This feature seems fatal to the general application of the Daly hypothesis of limestone assimilation, and consequently more detailed analyses are indispensable if the origin of the alkali rocks is to be intelligently discussed. It is disappointing to find in the majority of petrological papers analyses that are copious in number but deficient in detail. Petrologists should insist on all the detail they can get, for even the rarity or absence of a minor constituent is likely to be evidence of positive value. The high standard in this respect reached by the analysts of the Geological Survey of Great Britain, and particularly by Dr. H. F. Harwood, of the Imperial College of Science and Technology, is already directing attention to problems of fundamental importance that cannot as yet be adequately discussed on a world-wide scale for lack of the necessary data.

Dr. Washington's book is of particular value because of his insistence on a high ideal of accuracy and completeness. If time be a consideration, it is well that the petrologist and his chemical colleague should realise that a few detailed analyses are worth very much more than a large number that stop after twelve or fourteen constituents have been determined.

ARTHUR HOLMES

### Language through the Looking Glass

*Through Basque to Minoan Transliterations and Translations of the Minoan Tablets*. By F. G. Gordon. Pp. v + 83. (London: Oxford University Press, 1931.) 10s. 6d. net.

IN this book the experiment is tried of assigning modern Basque values to the Minoan characters on bronze age tablets from Crete. As Mr. Gordon says (p. 1), "such a method must obviously begin as pure guess-work." It also ends there, for "not only did the system yield a language indistinguishable (at present) from Basque, but it revealed unmistakable references to Hellenic deities, several old Greek names, and three poems, one in hexameter verse, one in elegiac, and one in couplets" etc. Basque is lovely for the purpose "the language is highly fluid, the aspirate is uncertain, and inversions are common" (p. 2), and

"it appears to make no distinction between B, F and M, T and N, G and K, L and R, O and U." It was also "an obvious convenience" that "the authors of the script were able to select signs with several meanings" (p. 3), and Mr. Gordon's "method", as he frankly says (p. 4), "consists in applying a series of hypothetical values, and endeavouring to show that they fit everywhere." For example (p. 9), with a sign which "appears to represent a conical eminence of some kind, and is provisionally rendered *iaq* or *iq*, Basque *ik* 'height'", he thinks it "possible to write the plural the agential suffix, the partitive suffix, the past participle, and the imperative singular, besides using the sign as a connecting link." English itself has never attempted as much, and it is not surprising that "it would constantly occur, therefore, as in fact it does." Another sign (for "beard, *bizal*, Basque *bizar*") "may also stand for a univalve of contorted type" (for which no Basque word is given), because it "stands as a decoration in a marine subject", being in fact what the Germans call a "Fullenornament" of the commonest, in Late Minoan pot-painting.

The proof of the pudding is, however, in the eating. A well-known tablet (Hull, "Ægean Archaeology", pl. xxxiii) not only "tells a connected story" (p. 4), but tells it "quite in the spirit of the Greek Anthology." Scholars familiar with the Anthology must judge for themselves a composition which is "only what might have been expected from the Minoan genius." Here is this "epigram", an "elegiac Muopotmos", and "the work of a practised hand", of which "the rhythm goes with a swing" (p. 16). *A spider in its web, holding thread in its mouth, a flesh-fly, round-headed, flower-skinned, the little wine-jar tapper. Take care, drinker, embracing a tomb with the mouth, drinking wine—alas! alas! He has spun round, dead!* As Mr. Gordon says (p. 14), it is "a little disconcerting at first", but it is sober prose compared with the translation of the Phaistos Disc which he offers on pp. 55-67. This latter document, he thinks, is a metrical calendar, partly elegiac. Here is one of the pentameters *Yasah dad bidraq yadzua ullueduq izal*, and it means (through Basque to Minoan) "the lord, smiter of the horse-hide (or the surface of the rock), the dog climbing the path, the dog emptying with the foot the water-pitchers."
